on the sciences and arts collectively, dictionaries of on the solences and arts consciency, dictionaries of science and art, general transactions of philosophical societies; 2. Physical sciences; 3. Mathematical sciences; 4. Mechanical arts; 5. Military and naval arts; 6. Arts of design; 7. Art of writing; 8. Musical and histrionic arts; 9. Medical arts; 10. Domestic and recreative arts. VI. Literature and Polygraphy.— 1. General treatises on literature and literary composi-tions, histories of literature in general; 2. Linguis-tics or philology; 8. Poetry and fiction; 4. Oratory, or collections of speeches on various and miscellaneous subjects, and treatises on oratory; 5. Essays, proverbs, and literary miscellanies; 6. Epistolography, or col-lections of letters on various and miscellaneous subjects, and treatises on letter-writing; 7. Bibliography and literary history of particular countries; 8. Poly graphy (i.e. works on subjects extending over two or more of the classes comprised in this scheme). The works in many of these divisions are subdivided into ections, and these frequently into several sub-sections. if the books that they comprise are numerous. (See BIBLIOGRAPHY.)

CATALOGUE, in Astron., a term applied to denote a list of stars, in which their positions at a certain time are registered, according to their latitude and longitude, or right ascension and declination; and means are also given whereby the effects of aberration, precession, and nutation may be computed, and the position of the star in the heavens may be determined at any time. Catalogues are also given of the positions of the nebulæ and fixed stars, and the elements by which the places of the planets and asteroids may be determined. The instruments used in observing the position of the stars, in order to form a catalogue, are the transit-instrument, circle, and sidereal clock. (See CIRCLE, SIDEREAL CLOCK, TRANSIT-INSTRUMENT.) A catalogue of standard stars, by which the right ascension of others may be regulated, will be found in the "Nautical Almanac." Mention is made elsewhere of the principal catalogues of the stars from that of Ptolemy to

the present time. (See ASTRONOMY.)
CATALYSIS, kät-äl'-e-sis (Gr. kutaluo. I dissolve). Catalysis, or power of presence, is a term applied to the chemical action that certain bodies exert upon the chemical action that certain bodies evert upon others, without themselves taking part in the chemical changes resulting therefrom. Thus, yeast converts sugar into carbonic acid and alcohol, without itself entering into the composition of either of these bodies. Examples of this occur in many of the ordinary operations of the laboratory. Chlorate of potash, for instance, melts at 650° Fah., and if the heat is raised to 900° Fah it is decomposed and gives of overgon. 700° Fah., it is decomposed and gives off oxygen; but, if mixed with one-fourth of its weight of black oxide of manganese or copper, oxygen is evolved below 450°.

The term catalysis must be looked upon as merely applied to certain actions, the nature of which is imperfectly understood, and not as implying a special force. Most of these actions may be ascribed to other well-known causes. Mr. Merce, for instance, explains the action of certain metallic oxides on chlorate of potach by supposing that the particles of the exide attract the oxygen contained in the salt with sufficient force to cause its liberation, although the force is not sufficient to effect their union. (For a full elucidation of the most modern views upon this subject, see a paper read by Brodie before the Royal Society, and published in part II., p. 750, of the Philosophical Pransactions.

CATAMARAN, kā-tām-ā-rān', in Mar., a sort of float.

#### Catarrh

of which serves as a keel, the other two as sides. rower stands or kneels in it, and paddles with a piece of bamboo. It is used on the coast of Coromandel,

of bamboo. It is used on the coast of Coromandel, and particularly at Madras, for the conveyance of letters, messages, &c., to the shipping in the roads.

CATAPAN, or CATIPAN, kill-d-pln (Gr. katepanes, captain), a name given by the Greeks in the 12th century to the governor of their dominions in Italy.

CATAPHRYGIANS, kill-d-frij-gins, a sect of hereties that arose in the Christian church in the 2nd century, and required their name from the country of Phryria. and received their name from the country of Phrygia, in which they first made their appearance. Their founder was one Montanus, a native of Mysia, who, after his conversion to Christianity, became subject to trances, in which he uttered what were supposed to be

prophecies, as did also Priscilla and Maximilla, two ladies of rank who joined him. (See MONTANISTS.)
CATAPLASH, kät-ä-plazm (Gr. kataplasso, I beamear or cover with a plaster), in Surg., is a poulties or external application of a pulpy consistence, employed for removing inflammation, promoting suppuration, or relieving pain. They are of various kinds, and may be composed of a great variety of substances, according to the purpose they are intended to serve, being emollient, stimulating, astringent, discutient, antiseptic, anodyne, &c. The common linseed poultice is in all ordinary cases the best that can be used. It is formed ordinary cases the best that can be used. It is formed by gradually stirring the meal into a sufficient quantity of boiling water until the mass has acquired a proper consistence. It is then inclosed in a piece of muslin or thin calico, and applied to the part as hot as it can be borne. The bread poultice is also very useful, though inferior to the former. It may be made either of milk or water, the bread being crumbled in, and the mass allowed gently to simmer over the fire till properly softened, and then beat and stirred about with a groot till of the proper consistence. A cold with a spoon till of the proper consistence. A cold bread-and-water poultice is sometimes used to allay inflammation. Among the other substances employed in the making of poultices are oatmeal, mustard, vinegar, yeast, charcoal, hemlock, digitalis, alum, sagar of lead, carrot, and sorrel. Considerable care is necessary in making the poultice of the proper consistence. It should be sufficiently thick to maintain a certain form when applied, and yet to accommodate

itself easily to the part.

CATAPULTA, kät-ä-pul'-tä (Gr. kalapeltes), an engine of war of great power, used by the ancients for throwing large darts and arrows against the enemy, as the balista was used for throwing stones. It resembled a strong was used for informing issues. It rescribes a strong short bow placed it a frame of wood, securely planted in the ground. The cord was attached to a flat piece of wood, which worked on a slide projecting to the rear. The bow was bent by the action of a small windless at the extremity of this projection. When the cord was suddealy released from the extreme tension to which it had been subjected, the recoil of the bow returning to its original position, hurled the arrow forward with great force. The catapulta is said to have been in-vented by Dionysius, the tyrant of Syracuse, in Sicily,

about 400 B.C.

CATARACT. (See EYE, DISEASES OF THE.) CATARACT, kat-a-rakt (Gr. kuta, downwards; rame, I dash), in Hydrog, a precipice in the channel of the river, caused by rocks or other obstacles stopping the course of the stream, from whence the water falls with a greater noise and impetuosity. The English language has many words that express the different degrees of rapid and sudden descent in streams of water. The term most generally used is falls. Many cataracts are remarkable for their picturesque sublimity. The falls of Niagara, in America, surpass, in size and grandeur, all others in the known world.

all others in the known word.

CATABRI, or Colp, kil-tar' (Gr. katarrhes, I flow down), is the most common of all the disorders to which the human body is subject, more particularly in variable climates, like our own. There are two kinds variable climates, like our own. There are two kinds of this disease,—the one a common cold; the other influenza, or epidemic cold. (For an account of the latter, see INFLUENZA.) A common caterrh is an inflammatory state of the mucous membranes of the head or chest. In the former case it is called cold in the head, or conyza; in the latter, cold on the chest, or bronchitis (which see). The symptoms of a cold in the head are a sense of uneasiness, heat, and stuffing

## Catestrophe

in the nostrils, diminution or loss of smell, dull, heavy pain in the forehead, inflamed eyes, succeing, and a slight impediment in breathing. Generally, it extends also to the throat and chest, occasioning hoarseness, cough, and difficulty of breathing. Frequently there is also a general derangement of the system, loss of appetite, lussitude, chilliness, succeeded by dry feverish heats and stiffness of the joints. The nostrils discharge a fluid at first thin and scrid, but which afterwards becomes thicker, and often purulent. The comwards becomes thicker, and often purulent. The common cause of this disease is exposure to a cold or damp mon cause of this disease is exposure to a cold or samp atmosphere, or to draughts, especially when the surface of the body is warm or perspiring. It is frequently occasioned by passing directly from a warm into a cold atmosphere, and we believe, even more frequently by passing immediately from a cold into a warm atmosphere. Indeed, any sudden atmospheric change is apt, in delicate persons, to produce cold; but in passing from a warm room to the cold air, people generally take some care, though they are not generally aware that the like danger attends passing directly from the cold air into a heaved room, and, hence, do not provide against it. The treatment of a common cold is usually a simple matter. Confinement to the house for a day or two, a warm foot-bath, diluent drinks, abstinence from animal food and vinous or other fermented liquors, and a dosc or two of some gentle laxative, are usually sufficient to remove the disease. There is also what is called the dry method of cure, which has the advantage of not requiring confinement to the house, though, otherwise, some might be inclined to regard the cure as worse than the disease. It consists simply in abstinence from every kind of drink, no liquor, or next to none, being allowed until the disease is gone. Dr. Williams, its inventor, states that the necessary privation is not hard to bear, and that a cure is effected, on an average, in forty-eight hours. He allows, without recommending, a table-spoonful of tea or milk for the morning and evening meals, and a wine-glassful of water at bedtime. The principle acted upon is that of cutting off the supply of watery materials to the blood, and thus leaving nothing to feed the secretion from the inflamed mucous membrane. The best preventive against cold is the daily use of the cold bath, and this is the best means that can be adopted by those who have an habitual tendency to this disease. It should, however, be begun in summer, and the water ought to be at first tepid; but, after being begun, the practice may be continued throughout the winter.

CATASTROPHE, kit-ta'-tro-fe (Gr. katastrophe, from kata and strephein, to turn), is a turning about, a revolution, and generally applied to the final turn or change of events, the change which produces the final event. In ancient dramatic poetry it was applied to the fourth and last part of the play, or that immediately succeeding the catatasis; the whole drama being divided into

protasis, epitasis, catatasis, and catastrophe.

Cat-Bind (Turdus felivox), a species of American thrush, of the same group as the mocking-bird, which it closely resembles in its vocal powers and its courage in defence of its young. It feeds on fruit and berries of all kinds, worms and insects, and builds its nest in the most conspicuous manner, generally in the neighbourhood of human habitations. It derives its name from its peculiar mewing cry when disturbed in its nest.

CATCH-WORD, kitch-ward, among printers is the word placed by itself at the bottom of each page, as being that with which the next page begins. This system is now not much in use; but it is still sometimes employed in writing, particularly in deeds and other formal documents.

CATRCHESIS, kid-e-ke'-sis (Gr. katechesis), is used in a general sense to denote instruction in the rudiments of any art or science, more particularly in the first principles of the Christian religion. It is derived from the Greek verb katecheo, which signifies to sound or ring, and also to ring a thing in one's ears, or to teach orally; and hence, etymologically and originally, catechesis denoted instruction communicated orally in the first principles of the Christian religion. In the primitive church it was the instruction communicated visid received in the condition of the Christian religion. In the primitive church it was the instruction communicated visid the church it was the instruction were called catechists, and the recipients catechimens.

# Categorical Proposition

Carsoniss, kill-e-kize', is to instruct by asking quantions; to examine. In education this is one of the best ways of communicating instruction to the young, and of disciplining their mental powers. By this means their attention is excited and kept up, their knowledge is fixed in their minds, and they are taught to give expression to their thoughts. Unfortunately, however, the mode pursued by teachers is too often not that best suited for the purpose. Instead of having for their object the establishing and adding to the knowledge which he scholar already has, they appear rather best upon despoiling him, and making him doubtful of every particle of knowledge which he possesses; the mode of proceeding being very much like that by which a counsel attempts to bamboozle a witness for the opposite side. It has been well said that "a boy may preach, but it requires a man to catechies."

CATECHISM, kit'-e-kizm, generally denotes an elementary bock, containing the rudiments of any art or science in the way of question and answer; more particularly it is applied to such a work on the simpler doctrines of religion. Catechisms for children should be framed so as not to puzzle and confound, but to conveyinstruction by degrees, and to proceed from the simplest and most elementary principles to the more profound. The earliest catechisms of the Church consisted of no more than a repetition of the baptismal vow, the Creed, and the Lord's Prayer; and these, together with the ten commandments, constituted at first that of the Church of England. Afterwards James I. commanded the bishops to add to it a short and plain explanation of the sacraments, which was accordingly done by Bishop Overall, then dean of St. Paul's, and approved by the rest of the bishops. This is one of the best catechisms in existence, being alike remarkable for its brevity, simplicity, and freedom from sectarianism. The Shorter Catechism of the Westminster Assembly of divines, which is that adopted by Presbyterians, and taught in simues tall the schools of Scotland, is admirable as a comperdium of theology, but is much too profound, and goes too far into the regious

CATECHU, kât'e-ke'u (Jap. kate, a tree, chu, juice), called kut or kutch by the natives of India, is properly an extract prepared from the inner brown-coloured wood of the Acacia Catechu; but the term is now applied also to other extracts similar in appearance and ropperties. Some of the catechu of commerce is prepared from the kernels of Areao Catechu, and a kind called Gambir, or Terra japonica, from the leaves of Uncaria Gambir. The substance is largely employed in the arts of dyeing and tanning, and medicinally as an astringent. It is imported in roundish balls or square pieces, varying in colour from a pale whitish or light reddish-brown, to a very dark brown. The dark-coloured catechu from Pegu is said to be the most powerful of all vegetable astringents. Catechu contains a large proportion of tannin, very similar in properties to that of galls; also a peculiar principle called catechine. (See ACALA, AREA, UNCARIA.)

CATECHMENS, Aktec. ku.-mens, were the lowest order of Christians in the primitive clurch, and were admitted into that order by the imposition of hands and the sign of the cross. The time of their continuance in this state varied at different times and in different places; and frequently it depended upon the proficiency of the catechumens themselves. Though regarded in some measure as Christians, yet they were not even permitted to see the celebration of the cucharist. There were four orders of catechumens.

1. The Exchoumenoi, or those receiving instruction privately without the church, and not yet allowed to enter it; 2. the Audientes, who were admitted to hear sermons and the Scriptures read in church, but not allowed to partake in the prayers; 3. Genuficetonies, so called because they received imposition of handskineeling; 4. Competentes and Electi, the immediate

allowed to partake in the prayers; 3. Genificeteness, so called because they received imposition of hands kneeling; 4. Competents and Electi, the immediate candidates for haptism.

CATHGORICAL PROPOSITION, kill-s-gor'-s-kill, in Log., is a proposition which affirms or denies absolutely, without any condition. They are of two kinds,—pare, such as assert simply one thing of another, as the king reigns; and modal, such as assert one thing of another under a certain mode or form, as the king reigns justify. (See PROPOSITION.)

## Categories

Catherine Wheel

CATEGORIES, kat's-gor-ees (Gr. kategoria, from kategoreo, I declare or predicate), in Log. and Met., is a term applied to an arrangement or distribution under a term applied to an arrangement or distribution under certain heads, of all that may be said or predicated of any object of human thought. According to Aristotle, who enters fully into this subject in his "Organon," all the objects of our thought are comprised in the following ten categories:—1. Substantia, substance; 2. Quantities, quantity; 3. Qualities, quality; 4. Relatio, relation; 5. Actio, action; 6. Passio, passion; 7. Ubi, where; 8. Quando, when; 9. Situs, position; 10. Robitus, possession. Philosophers are much divided in opinion as to the utility of these categories, some researching them as worthless, others of great value. regarding them as worthless, others of great value. According to Harris, "there are few theories so great, so comprehensive, so various, as the theory of these categories: in contemplating them we see whence the sciences and arts all arise,—history out of substance; mathematics out of quantity; optics and medicine out of quality and quantity; astronomy, music, and meshanies out of quantity and motion; painting out of quality and site; ethics out of relation; chronology out of when; geography out of where, &c." The Categories of Aristotle are, in truth, a metaphysical and not a logical reduction, and are methodically deduced and simplified by Sir W. Hamilton, in his edition of Reid's works, p. 687. Mr. J. S. Mill, who objects to Aristotle's classification, attempts another of his own, as follows: -1. Feelings, or states of consciousness; 2. the minds which experience those feelings; 3. the bodies or external objects which excite all that class of feelings which we call sensations; and 4. the successions and co-existences, the likenesses and unlikenesses, between feelings or states of consciousness. The categories of Kant are purely subjective, being merely a gories or Rant are purely subjective, being merely a classification of the conceptions or judgments of the understanding. They are—1. Quantity; 2. Quality; 3. Relation; and 4. Modality. 1 at the first he include unity, multitude, totality; in the second, reality, negation, limitation; in the third, substance and accident, cause and effect, action and reaction; and in the fourth, possibility, existence, necessity.

Compart Efficient (Gr. archau) in Ribblical Criticism.

CATENA, kät'-e-na (Gr., a chain), in Biblical Criticism, is an exposition of a portion of Scripture, formed from collections out of several authors; such as the "Catene" of the Greek fathers in the "Octatench" by Procopius; the "Catena Aurea" of Thomas Aquinas.

CATESTILLAR, kill-or-pil-lin, the common name given to the larve of the lepidopterous insects, butter-flies and moths. There is as great a variety in the form of caterpillars as in the insects to which they change. Each family, genus, and species may be dis-tinguished by its characteristics. The bodies of cater-pillars are generally long, nearly cylindrical, and di-vided into thirteen segments, of which the auterior forms a horny head, furnished with jaws and antenne, and neually with groups of simple eyes. On each side of the body are nine spiracles, or small openings for respiration. The mouth of the caterpillar is usually respiration. The mouth of the caterpliar is usually furnished with strong jaws, capable of tearing, cutting, and masticating the substances on which it feeds, which are very varied in their character, although they entirely differ from the substances eaten by the perfect insect. The first three segments of the body are each furnished with two feet, which represent the six feet of the insect into which they change. All the feet or legs are very short. When the caterpillar has arrived at the proper stage to undergo its metamorphosis, it at the proper stage to undergo its metamorphosis, it seeds some seculated spot. Some species find a retreat in the hollows of the barks of trees, others in the walls or wooden palings of the garden, while a few species bury themselves in the earth. Fortunately for the agriculturist, a great quantity of the lepidopters are destroyed by parssites, which lay their eggs in the larves. The caterpillar undergoes two changes, firstly the testing the secretar united. to the pure state, then to the perfect winged insect. (See Burreners, Morn.)

CAPONY STRINGS, kill-gat, strings prepared from the intestines of sheep for musical instruments, bow-atrings, hatters' bow-strings, clockmakers' cords, and thougs for whips and laces for boots. The intestines are first cleaned and freed from fatty matter, and the

next drawn through a plate perforated with holes, fumigated with sulphur, and sorted according to size. The strings known as "Roman strings" are the beat for violins. They are made at Milan, and are distinguished for their strength and transparency. They are generally formed of two separate pieces twisted together, and great pieces twisted together; and great nicety is necessary in conducting the process of fumigation to which they are subjected, lest they become too brittle if exposed for too long a time to the action of the sulphur, or liable to be frequently out of tune if not exposed long enough.
Larger strings are made by twisting several lengths of
catgut together until the required thickness is obtained. The intestines of other animals have been tained. The intestines of other summas nave been used for making a coarse but strong cord for turning lathes and machinery; but those of the sheep only have been found to furnish strings suitable for musical

nave been found to turnish strings strings at the same and philosophiead purposes.

CATHA, kā'-thit, in Bot., a gen. of plants belonging to the nat. ord. Celastracess. The most important species are C. calulis and spinosa, two shrubs flourishing in Arabia. The young shoots, with the leaves attached, of these plants constitute the famous drug called kat. of these plants constitute the famous drug called kat, khat, or kafta, which is chewed by the Arabs, and is said to produce great bilarity of spirits and an agree-able state of wakefulness. A decoction is also made from it and used as a beverage, like our tea: its effects are described as being somewhat similar to those produced by strong green toa.

CATHARI, ka-thari-re (Gr. katharoi, pure), in Eccl. Hist., was a name given to several sects of Christians who made professions of greater purity in life or doc-trine than others. It was chiefly applied to the No-vatians; but was given afterwards to various sects, known in France and other countries as Albigenses,

Paterini, Paulicians, &c.

CATHARTICS, ka-thar'-tike (Gr. kathairo, I purify), in Med., is a term applied to such substances as, taken in aned, 18 a term applied to such stortainers as, taken internally, cause a special irritation of the intestigal canal, and increase the alvine evacuations; in other words, have a purgative effect. Cathartics act upon the system in various ways, and have been variously divided; as, into stimulating, as jalay, aloes, colombia. cynth; refrigerating, as Glauber or Epsom salts; astringent, as rhubarb; emollient, as castor-oil; narcotic, as tobacco or henbane. One kind is preferable to another according to the circumstances of cach individual case.

nativatal case.

CATHEDEA; kä-the'-drå (Gr., a sent), denotes, in a general sense, a chair: more particularly, a professor's chair, or a preacher a pulpit; and is also used for a bishop's see or throne in a church. Hence, to speak ex cathedrá, is to speak with authority, as a bishop from his throne.

from his threac.

CATHEDRAL, ká-the'-dral, is a church in which the bishop's throne or seat (cathedra) is placed, and which is thus the chief or principal church in the diocese or district. It has usually, also, a dean and body of canons or prebendaries; but this is not essential to constitute a cathedral church, nor is every church that has a chapter of canons a cathedral. (See BISHOP, CANON.) The cathedral church is the parish church of the whole diocese, which, in early times, was commonly called parochia. In Engined no diocese has more than one cathedral, but there are numerous instances of a plurality of cathedrals even in the same The cathedral church is the parish church city, on the continent, particularly in Italy; as at Rome, Milan, &c. The normal plan of an English cathedral is in the form of a Latin cross, that is, a cross whose transverse arms are less than the longitudinal limb. Generally, its several parts are suffi-ciently distinguished as nave, choir, and transept, with asiles, western towers, and central tower; but in more minute description, especially where ritual arrange-ments are concerned, these terms are not always sufficiently precise; and in order to arrive at a more exact nomenclature, it is necessary to trace the changes in a cathedral church from the Norman period to our own (for which see Hook's "Church Dictionary"). The cathedral service is the usual Church of England ser-

vice, intoned, with an anthem and the Fashus chanted, CATHERINE WHEEL, kith's-rine, a circular window, or portion of a window, frequently found in esthedrals and churches built in accordance with the Gothio style external membrane removed. They are then souked, or portion of a window, frequently found in cathedrals and the inner membrane is taken away, after which and churches built in accordance with the Gothio style they are soaked in a solution of potash. They are of architecture. When the entire window is circular

Oatheter

Cours

in form, it is generally found at the east end or in the gables of the transcots. In some of the cathedrals in gables of the transcots. In some of the cathedrals in France, windows of this description are found of great diameter, divided into compartments by stone tracery elaborately chiselled into a variety of forms, and some-times by shafts radiating from a circular centre. The name is taken from the instrument on which St. Catherine of Alexandria suffered torture and death, A.D. 307,

erine of Alexandria suffered torture and death, A.D. 307, for her persistent adherence to the Christian faith.

CATHETER, kāth-e-ter (Gr. kathiemi, I put down or into), in Surg., is the name of an instrument employed for drawing off urine by introducing it into the bladder. It is a long tube, usually formed either of silver or gum-elastic, open at the handle, and having at the sides, near the point, holes or eyes into which the urine flows, and is thus carried off. Those for males are usually from ten to eleven inches in length, and considerably curved towards the point; those for females are much shorter and nearly straight. The males are much shorter and nearly straight. The introduction of the catheter is an operation requiring a considerable degree of tact and skill, and should be

done with great caution.

One with great caution.

On the constant caution.

On the constant caution.

All substances susceptible of direct decomposition by the electric current are called electrolytes, according to Faraday. Those elements which are evolved at the anode are termed anions, and those which are evolved at the cathode, cathions. when water is electrolyzed, two ions are evolved,oxygen, which is the anion, and hydrogen, the cathion. (See ELECTROLYSIS.)

CATHODE, kö'-thode (Gr. kata, from ; odos, a way), a term introduced by Faraday to designate the negative pole of any electrical arrangement for decomposing a chemical compound; the cathode, in other words, is the surface by which the electric current leaves the body undergoing decomposition. (See

ANOBE, ELECTECLYSIS.)
CATHOLIC, käth'-o-lik (Gr. katholikos, general, universal), a term first applied to the Christian church to distinguish it from the Jewish, which was confined to one nation or people. Afterwards, when sects and heresies arose, taking to themselves particular names, those who remained orthodox and adhered to the Church, called themselves Catholics, i.e. members of the Church general or universal. Hence, the Roman the Church general or universal. Hence, the Roman church now calls itself by the name of Catholic, regarding itself as the only true and orthodox church, and holding that all who have separated from her are acctarians and hereities. (See ROMAN CATHOLICISM.)

The seven Catholic episites are those of James, Peter, Indee and Laboratorian as called matchible. Jude, and John, and are so called probably because they were not written to any particular person or church, but to Christians generally. The title of Most Catholic Majesty is borne by the kings of Spain.

CATROLIC EMANCIPATION ACT. (Sec ROMAN CA-

THOLIO EMANCIPATION ACT.)

CATKIN. (See AMENTIM.)
CATOFFEICS, kil-toy'-triks (Gr. kateptron, a mirror), that part of optics which treats of the reflection of light from the regularly-formed surfaces of such of light from the regularly-formed surfaces of such bodies as water, glass, and the metals. The name of speculum, or mirror, is generally given to those substances which have a lighly-polished and regularly-formed surface; but, in general use, the term speculum is applied to a metal reflector and mirror, to a reflector made of glass, and coated with an amalgam of times a supplied to the surface of metal reflector made of glass, and coated with an amalgam of times. and mercury or a layer of pure siler. There are four kinds of reflectors used in optics,—the plane, the convex, the concave, and the cylindrical; and when a ray of light is incident upon any of these surfaces, its re-flection is always governed by the same laws. These laws, which are the result of observation and experiment, form the groundwork of entoptries. They are as follows:—First, that the incident ray, the normal to the surface at the point of incidence, and the reflected ray, are all in one plane; second, that the angle of reflection is always equal to the angle of incidence. (See OPTICS.)

CATOPTROMANCY, ka-top'-tro-man-se (Gr. katoptron, a mirror, and manteia, divination), a species of divina-tion among the ancients by means of a mirror. It is said that among the Achaians, a sick person was wont to let down a mirror by a thread into a fountain before the temple of Ceres, and if, on looking into the glass, 407 his countenance appeared ghastly and distorted, it was regarded as an ill omen; but if fresh and healthy, as an indication that he would recover.

CAUCUS, kaw'-kus, a term used in America to den a political meeting of a party for the purpose of agree-ing upon candidates to be proposed for election to offices, or to concert measures for supporting certain candidates. The origin of the term is doubtful.

CAUDEX, or STIFE, kaw'-dex (Lat. awdo, I out, because, by cutting off the branches, what remains, congrowing) stem of a tree-fern. The candex often rises to the height of fifty or sixty feet, bearing on its same to the height of fifty or sixty fect, bearing on its sammit a crown of foliage. It produces no lateral branches, but is covered with scars produced by the successive whorls of leaves or fronds which have fallen during the life of the plant. The stem is of uniform diameter from near the base to the top.

CAUDLE, kaw'dl. [Fr. chaudeau, from Lat. calidus, warm), is a kind of warm broth, composed of gruel, warm, or her saver and gried and greet to the side.

warm), is a sind of warm oroth, composed of gruel, wine or beer, sugar, and spices, and given to the sick.

CAUI, kawl (Lat. caula, a fold), is a thin membrane, sometimes found encompassing the head of a child when born. This was formerly regarded with great superstition, it being held to denote that the child so born would be very fortunate and escape many dangers.

A caul was also believed to confer the like benefits upon its possessor; and hence they were frequently sold at a high price. They were regarded by seamen as an infallible preservative against drowning. Even so late as 8th May, 1848, an advertisement appeared in the Times, offering, for six guineas, a child's caul, " for which fifteen pounds was originally paid, was affect with its late owner thirty years in all the perils of a senman's life, and the owner died at last at the place of his birth.

Of his Office.

CAULESCENT, kawl-es'-ent (Lat. caulis, a stalk), in
Bot., a term applied to plants having evident stems.

CAULIFLOWER. (See Brassica.)

CAULIS (Lat.), in Bot., the term applied to the stem of an herbaccous plant which dies down annually to the

surface of the ground.

CAUSE, kawze (Fr. cause; Lat. causa), in ordi-ary language is understood to be that by which something known as the effect is produced, and with-out which it could not have existed. Aristotle diout which it could not have existed. Aristotle di-vides causes into four different kinds,—the material, formal, efficient, and final. The first is that of which anything is made, as the brass or marble of a statue. The formal is the form, idea, or pattern of a thing, as the artistic idea or plan of the statue. The efficient cause is the power acting to produce the work, as the mechanical labour employed in producing the status. The final cause is that which led to the production of the thing, as the end or motive in view in the making of the statue. As will be seen from the examples give it is possible for one object to combine all the kinds of causes. Causation, causality, or the action of a cause in producing an effect, is one of the most disputed points within the region of metaphysics. There is believed to be some connection between cause and effect; but the utmost scrutiny has never been able to discover any power by which the cause operates. Experience only teaches us how one event consequently follows another, without instructing us in the secret connection which binds them together. We believe that a cause is something which not only precedes, but has power to produce the effect. The various opinious as to the nature and origin of the principle of causality in the human mind are ranged by Sir W. Hamilton into the causal cause is the contract and cause is the convenienced. into two great categories,—the one comprehending those theories which consider this principle as empirical, or a posteriori,—that is, as derived from experience; the other, those which view it as purs, or a priori,— that is, as a condition of intelligence itself. These two primary genera he subdivides into several subordinate classes.—(See Lectures on Metaphysics, vol. ü. p. 385, seq.) He attempts to explain it by what he terms "the law of the conditioned," or the law of limitation: that we are unable, on the one hand, to exceeive of nothing becoming something; and, on the other hand, of something becoming nothing; that we are utterly unable to realize in the possibility of the complement of existence in the universe being either increased or diminished. Ex nikilo nikil, is nikilum and

# Causes, Final

posse reverti, expresses, according to him, "in its purest form, the whole intellectual phenomenon of purest ferm, the whole intellectual phenomenon of causality." This explanation, however, is not gene-rally received by philosophers.

CAUSES, FINAL, DOCTRINE OF, which, with Aristotle, was merely an inquiry into tendencies, has, by the theologians of modern times, been employed to establish the truth of a divine providence. The argument from final causes, according to Dr. Reid, when reduced to a syllogism, has these two premises:—1. That design and intelligence in the cause may, with certainty, be inferred from marks or signs of it in the effect; and 2. that there are the clearest marks of design and wisdom in the works of nature; the conclusion being, that the works of nature are the effects of a wise and intelligent cause. The remark of Lord Bacon, that final causes are sterile, has frequently been quoted.
"They are sterile," says Dr. George Wilson, "for the same reason as the vestal virgins were; namely, that they belong to God." "Gentle, solemn, and beautiful, they attract men, and modestly permit them to look on their features; but awe mingles with admiration in the gazer's heart, and the ever-burning fires on the vestal altar forbid all close and impious approach. Nevertheless, we must seek after and love final causes even with a lover's passion, although in this life they never can be ours." They are "the most perfect of earthly witnesses to the being and perfections of God.

-Edinburgh University Essays.

CAUSEWAY, kawz'-way, or kawz'-e (Fr. chaussée), a pathway that is raised above the level of the ground. This rame is given to the raised sides of a street that intervene between the houses and the roadway, the outer edge of which is formed by strong blocks of stone called curbstones. (See Curb.) The causeway is gene-rally paved with flat broad flagstones, and sometimes with pebbles set on edge, and rammed tightly together. Canseways are often formed by the sides of roads, for the convenience of foot-passengers, by throwing up a low level bank of some breadth, and along the marshy banks of rivers. In the latter case, faggots are laid down on the yielding soil, and a thick coating of earth and gravel is thrown upon them. A part of the north coast of Antrim, Ireland, between Bengore Head and the mouth of the river Bush, is called the Giant's Causeway, being formed of flat terraces of columnar basalt.
CAUSTIC, kaws'-tik (Gr. kaustikos, from kaio, I burn),

in Med., is applied to such substances as burn or de-troy the skin and flesh by acting chemically upon them. The caustics principally used in practice are the nitrate of silver, or lunar caustic, and potassa fusa,

common caustic, or caustic potass.

CAUTERY, kaw-te-re, in Surg., is a burning or searing of morbid flesh by a hot iron or by caustic medicines, the former mode being termed actual cautery, the latter potential cautery. Caution, kaw'-shun, in Scots Law is an obligation by

which a party binds himself as surety for the perform-

CAVALCADE, kās-āl-kaid' (Fr.), a procession or march
of persons on horseback; a formal, pompous march or cession of horsemen and equipages by way of ceremony, or as a means of gracing a triumph, or wel-

victorious warrior, &c.

CAVALEER, kib-a-leer' (Fr.), in English history was
the name given to those who adhered to the cause of
Charles I., as distinguished from the Roundheads, or

friends of the Parliament.

CAVALTER, in Mil., a work of defence raised on the level of a bastion or curtain, about ten feet above the nampart of the work, with a rampart of its own about wir feet in height. The height of the cavalier must wix feet in height. The height of the cavalier must depend on that of the eminence it is intended to com-hand. The sides should be parallel to the faces of the work on which it is constructed : formerly it was made in the form of a semicircle. The object of this defensive work is to gain height to command any rising ground from which the enemy might direct a fire into the fortifications, and to pour a plunging fire into their respines. Works raised by the attacking party on the facts of a fortification, consisting of a series of stops or and by a bank of earth revetted with gabions, from which are may be directed into the common way, are tronch cavaliers.

## Cavalry

CAVALEY, kav'.dl-re (Fr. cavalerie, from obeval, whose; ital. cavalere, a horseman or knight; Sp. cabalero, a horseman; Lat. cabalkus, a horse), a mame applied generally to soldiers mounted on horseback. The British cavalry consist of thirty-one regiments, of which two are called Life-guards, one Horse-guards, seven Dragoon guards, of which the 6th are distinguished as Carabiniers, and twenty-one ordinary dragoon regiments, which are classed as Dragoons, Lightdragoons, Lancers, and Hussars, as follows:—Dragoons, 1st, 2nd, 6th; Lancers, 5th, 9th, 12th, 16th, 17th; liussars, 3rd, 7th, 8th, 10th, 11th, 13th, 14th, 15th, 19th, 19th, 20th, and 21st. The English cavalry are superior in weight to, and better mounted than, any cavalry in in weight to, and better mounted than, any cavalry in the world. At Waterloo the French cuirassiers could not for a moment withstand the charge of the lifeguards, for man and horse were overturned by the impetus with which the household cavalry was launched against them, and literally ridden over by them. A regiment of dragoons consists of eight, and sometimes ten troops, of about eighty meneach, including non-commissioned officers; each troop has a captain, lieutenant, and cornet; and two troops form a squadron, and four squadrons a regiment. The term dragoon is derived from the weapon with which the French cavalry were armed, that were raised about 1600 by the Mareschul de Brissac, to surpass the famous German reiters, who were skilled in the use of the pistol on horseback. This was a short blunderbuss, with the muzzle formed like the yawning jaws of a dragon; whence those that were armed with it were called dragoniers, and then dragoons. The other names applied to English cavalry namely, lancers and hussars-have also been derived from foreign troops, the former being in imitation of the Polish lancers of the French army, who were armed with a long lance, and the latter from the hussars, or houssards, a species of light cavalry that formed part of the national armament of Poland and Hungary With the exception of the lancers, who carry a lance sword, and pistols, the English cavalry, both light and heavy, is armed with sword and carbine. The cavalry carbine is now a short breech-loading rifle, sighted for The average annual cost of a cavalry regi-600 vards. ment, including horses, is considered to amount to £25,000. The price of a horse is about £20 or £25, and it costs as much more to train him and render him fit for service. Cavalry, in latter times, have been all-important in confirming and securing a victory, by pursuing the flying foe, and turning what might otherwise have been a retreat into a rout. But, in early ages, battles were mainly fought with cavalry, who were enrolled from among the nobles and the more wealthy part of the population. The natural features of Greece rendered it impracticable for the Greeks to make their cavalry of similar importance to that of other nations, and they depended entirely on their infantry; but the Romans, although they paid great attention to the discipline and effectiveness of their infantry, had large bodies of caralry with every consular army, who were all men of good family and position. The cavalry of the Parthians was skilled in attack and flight when needful; they would lure on the foe by a feigned retreat, and bring down soldier after soldier with unerring aim while galloping at full speed on horseback. The cavalry of the Anglo-Saxons, and of the Huns, Goths, Vandals, and northern tribes that destroyed the mighty Roman empire, were justly famous, and composed the bulk of the armies of the day. The armies of the Middle Ages were composed chiefly of armics of the hiddle Ages were composed emerged cavalry, and, in the time of the Crusades, infantry were but little esteemed; but at Agincourt, Cressy, and Poictiers, the English bowmen did galant service, and, with the introduction of gunpowder and cannon into warfare, infantry and artillery began to equal cavalry in importance, and were soon considered more essential to bear the brunt of the battle. In the early part of the lath century, the cavalry of Poland, or Pospolits, as it was termed, consisted of the nobles and site of the kingdom, who were magnificently armed and accourted. Who does not admire the gallant volunteer cavalry of Charles I., that made such brilliant charges, punder Runer, the Monta of the date of cavalraged from under Rupert, the Murat of his day as a cavalry officer, against the stern iron-clad troopers of the Parliament. Many of the sons of these cavaliers, doubtiess, served in the Scotch Greys, the first regular regiment of

cavalry that was raised in England, by Charles II., in 1661. Since that time, the cavalry has always formed a distinguished arm of the British military service. The following are the distinctive duties of heavy and light cavalry in the British service:—The latter make gathering provisions, as well as in pursuit of a flying foe; while the former are used to cover the retreat of soe; while the former are used to cover the restrict of an army, and charge the enemy's cavalry and infantry, and capture his guus. It is considered that infantry formed in square to resist cavalry cannot be broken; but at the battle of Mohammerah, in Persia, March 26, 1857, British cavalry broke a square of Persian infantry, and rode through them; for Captain Wren, a man of gigantic size and power, who was foremost in the charge, having lifted his horse at the bristling line of bayonets, bove the men that held them to the ground under the weight of himself and his charger; thus enabling those who were at his heels to penetrate the square. When about to make an attack, the cavalry, like the infantry, are divided into the attacking force, the supports, and the reserve. Cavalry charge cavalry in line, infantry in column, and artillery in eckelon. (See ECDELON.) Its chief use is in pursuit or in covering a retreat, and an encounter with cavalry is a hand-to-hand combat, which is seldom the case with infantry, and can never

happen with artillery.
CAVEAT, kai'-re-at (Lat. caceat, let him beware; from careo), is a caption entered in the spiritual court, to stop institutions of clerks to benefices, probates of wills, administrations, and such like, from being granted without the knowledge of the party that enters it. The caveat being lodged or entered, the proceedings are thereby stayed, and the promoter, if he intend to proceed, must warn the other party to his caveat, who can then enter and dispute the right in a suit to be instituted for the purpose of trying it. If he fail to do so, the matter will proceed as if the caveat

had not been entered.

CAVES, or CAVERNS, kaivs, kiv-erns (Lat. caves, caverna, hollow), hollow places in the earth. They occur more or less along the rocky shores of all frectiowing seas, and are the results of abrasion by waves laden with fragments of stone, and acting upon preexisting fissures or the softer portions of the exposed rocks. The most celebrated caverns, however, occur in limestone strata, and appear to be the results partly of fissuring by subterranean disturbance, and partly of waste by the percolation and passage of carbonated waters. Some are celebrated for their great extent, waters. Some are described to their great strent, others for their gorgeons stalactites and stalagmites, and many for their treasures of sub-fossil bones. Among the most remarkable caverns may be mentioned, one in the limestone rock at Kirkdale, Yorkshire; those found in the carboniferous limestone of Chamorganshire, in which remains of British pottery have been found, in addition to bones of birds and beasts, which have been dug up more than eight feet below the present surface; and Fingal's Cave, in Staffa, an island on the west coast of Scotland, a fine example of a natural cavern in basalt or igneous rock. In the limestone strata of Derbyshire caverns are found lined with a calcureous deposit of brilliant whiteness, with pieces like icicles of great size hanging from the roof and rising from the floor. These pieces sometimes meet and form columns. Among the Derbyshire limestone caverns, Peake's Hole, near Castleton, Poole's Hole, and the Bagshaw Grottos, are the most remarkable.

CAVIARE, or CAVIAR, kar's airs (Sp. cabial; Arab.

gabier, from the Arab word gebara, signifying to press or strain, and season with fat), an article of food prepared in Russia from the roe of the sturgeon or some other large fish, and is mude by washing it in strong vinegar, and afterwards salting. The tasto for esting earlier is acquired; most people at first finding its "most ancient and fish-like smell" and oily taste very disagreeable. It is, therefore, only epicures who appreciate it: hence the proverb of "caviare to the multitude," which is applied to anything not likely to be appreciated by the common people.

CAVE. (See GUINEA-PIG.)

CAYENER PEPPER. (SeeCarsicum.)
CRANOTHUS, se-in-o'-thus (a name given by Theophrastus to a spiny plant), in Bot., a gen. of plants
belonging to the nat. ord. Rhamnacea. The young

shoots of C. americanus are used as an astringent, and in New Jersey the leaves are employed as a submittate for tea; hence they are commonly known as No Jersey tea.

CREIDE, se-bi'-de (Gr. kebos, a species of monkey), a term applicable to all the monkeys of the American

continent.

CERRIO, seb'-re-o, a fam. of coleopterous insects of sculiar structure. The body is of an oblong form, peculiar structure. The body is of an oblong form, arched above and deficaed in front; the mandibles curved, and entire at the tip. The thorax is broaded behind, and the antenne generally longer than the head and thorax. Some of these insects are remarkable for having the antennæ beautifully pectinated and of very great length.

CRCIDOMYIA, se-se-do-mi'-ü (Gr. kekidos, high-leap-ing; muia, a fly), small two-winged flies, that de-posit their eggs on the buds of growing plants. The best known is the wheat-fly (Cecidomyia visitei), that may be seen in immense masses flying about what folds shout I. wheat-fields about June. It deposits its eggs in the centre of the corolla, where the larva is hatched; and, by devouring the pollen, the plant is greatly damaged. When first hatched, they appear in the form of ting footless maggots, taper towards the head, and blunt at footless maggets, taper towards the head, and blunt at the hinder extremity, with the rings of the body somewhat wrinkled and bulging at the sides. They are at first perfectly transparent and colourless, but soon take a deep yellow or orange colour. The maggets, when fully grown, are nearly an eighth of an inch is length. It is said that they quit the wheatears at the beginning of August, and descend into the earth about half an inch below the surface, where they probably remain throughout the winter, making their appearance again in the shane of winced flies when the spring cora again in the shape of winged flies when the spring corn begins once more to show its head.

Degins once more to show its head.

CECHOPIA, see kro'-pi-d (after Cecrops, king of Athens, whose legs were fabled to be of snakes), in Bot., a gen. of plants belonging to the nat. ord. Artocarpaceæ. C. pelitata, a tree growing in the West Indies and South America, is remarkable for its stems being hollow except at the nodes. Owing to this peculiarity, the smaller branches are often used for making wind instruments.

CENTER (See CENTER)

CEDAR. (See CEDRUS.)

CEDAR-BIRD, sel-dür (Ampelis cedrorum), a native of America. The appellation of Cedar-bird is given to it on account of its partiality to the berries of the cedar. The passion of the cedar-bird for this diet cedar. The passion of the cedar-bird for this dies sometimes leads it into excesses, and, perhaps, premature death. As many as fifteen berries have been found in the throat of a single bird, "The nest is large for the size of the bird, fixed in the forked or horizontal branch of an apple-tree, ten or twelve feet from the ground; outwardly, and at the bottom, is laid. a mass of coarse dry stalks of grass, and the inside is lined wholly with very fine stalks of the same material. Inned wholly with very fine stalks of the same material. The eggs are three or four, of a dingy bluish white, thick at the great end, tapering suddenly, and becoming very narrow at the other; marked with small roundish spots of black, of various sizes and shades, and the great end is of a pale, dull, purple tinge, marked likewise with various shades of purple and black."

(Wilson's American Ornithology.) The tactics of the parent bird when disturbed in its nest are singular. On such occasious, the female at once flies off to a distance; it neither exhibits the least distress, nor utters a solitary cry of lamentation, and the intrader is left to examine the eggs or young at his leisure. The cedar-bird is largely consumed as an article of food, and at the end of autumn is, owing to its voracity, in prime condition. At this season a great quantity are sent to the markets. The colour of this bird is, on the upper parts, of a fawn-colour; the chin is black, and the abdomen and breast yellow. The wings are slaty-blue; the tail-feathers are rich yellow. Round the forchead there is a dark line, covering the eyes. It is about six inches and a half in length, and is rather a slim-built bird.

CEDAR-WOOD, OIL OF, an essential oil procured by distillation from cedar-wood at the rate of twenty-eight ounces to the hundredweight of shavings. contains cedrola, a white crystalline solid, and cedrene, a liquid hydrocarbon.

CEDAR-WOOD, TINCTURE OF, is readily made by

#### Cedrat

steeping the shavings of the wood in proof spirit. Mixed with a fourth part each of tincture of myrrh and rhateny, and flavoured with a few drops of oil of peppermut, it forms a valuable mouth-wash, termed "Ran Botol."

Capar, se'-deit, a perfume procured from the rind of the citron (Citrus medica) by expression and distillation. It is much used in the manufacture of scents, from possessing a peculiarly refreshing lemony odour. Extract of cedrat is made by dissolving two

odour. Extract of cedent is made by dissolving two ounces of the oil of citron in a pint of spirits of wine. Capazita, se'-dre-lā (from cedrus, the cedur-tree, its wood having an aromatic resinous seemt like it, in Bot., a gen. of tropical trees, the type of the nat. ord. Cedrelacca. C. Jobrifuga, C. Toona, and other apposies, have febrifugal and settingent barks, which have been used as substitutes for ciuchona. C. Toona trackers which is research in the company which is research. durnishes timber resembling mahogany, which is much used in the East Indies, and is occasionally imported into this country under the names Toon, Tunga, Poms, and Jees-wood.

CEDEBLACER, se-dre-lai'-se-e, in Bot., the Mahogany fam, a nat. ord. of dicotyledonous plants in the sub-class Thalamiflore, consisting of nine genera, including twenty-five species, chiefly natives of the tropical parts of America and India,—trees with alternate, pinnate, exstipulate leaves. The flowers are hypogynous and symmetrical; calyx and corolla with 4 or 5 divisions, both imbricated in astivation; stamens double the number of petals, with united or distinct filaments, and number or petals, with united or distinct filaments, and inserted on a hypogynous disk; owary usually 4 or 5-celled, with 4 or more ovules, and a simple style. The fruit is eapsular, with axile placentss; seeds usually numerous, flat, and winged. The plants of this order have aromatic, tonic, astringent, and febrilingal properties, and many of them are valuable timber-trees. Mahogany and satin-wood are products of the Cedrelance. (See Swiftment). Children valority. lacea. (See SWIETENIA, CHLOROXYLON.)

CEDRONE SEEDS. (See SIMABA.) CEDRUS, se'-drus (Gr. kedros), in Bot., the Cedar, a gen, of trees belonging to the nat. ord. Pinacer, subord. Abietex. The cedar of Lebanon (C. Lihani) has been celebrated from the earliest ages for its grave beauty, its longevity, and its magnitude; also for the excellence and durability of its timber. It is often alluded to in Scripture as an emblem of stability and prosperity. The grove of cedsrs on Mount Lebanon is about three-quarters of a mile in circumference; but of the four bundred trees now standing there are but the four number a trees now standing; there are but twelve of extraordinary age. One of these is sixty-three feet in circumference, and has possibly been in existence for some two thousand years. The cedar was introduced into England in the latter part of the 17th century, and one specimen at Sion House, London, is now eight feet in circumference at three feet above the ground. The Deodar, or Himalayan cedar (C. deodara), is also a magnificent tree, and is held in great veneration by the Hirdoos. The turpentine obtained from this species is much used in India for medical purposes, and is known by the name of Kelon-ke-tel.

Chiling, seel ing (Lat. ceilum, Fr. ciel, the heaven), in expression applied to the top or covering of a room, or any lofty building of great size, as a church. It is derived from words in the Latin and French languages that are used to denote the vault of heaven, which seems to cover that part of the world that lies within seems to cover that part of the world that lies within the circle of our horizon, in the form of an immense vault; and it is probable that the observation of this led to the adoption of the term. The ceiling is formed by nathing laths to the under surface of the joists that surport the floor of the story above or the beams of a roof, and covering them with two or three coats of plaster. The ceilings of churches are often semicircular in form, and divided into large squares by beams adorsed with bosses at the points of intersection, and that of the chancel is sometimes coloured blue and sdormed with bosses at the points of intersection, and that of the chancel is sometimes coloured blue and studded with stars. Flat ceilings are sometimes distincted in this way, and adorned with painting and pilding; and those of houses of the Tudor period are recoonly enriched with mouldings.

Charanta, si-me-li-d (fr.), was anciently applied to the carly Church denoted the sacred vessels and distincts belonging to the church. Hence, Ceimeliar-470

## Celibacy

cha, or Ceimeliophylax, was the officer, in ancient churches and monasteries, who had the custody of these things; and as rolls and archives were also under his charge, he was also frequently called Cor-tophylax, or Custos archivorum.

CELLERINE. (See CHELIDONIUM.)
CELLERINE, sel'-ā-rent, among logicians is a name
given to a mode of syllogism, in which the major proosition and conclusion are universal negatives, and the minor a universal affirmative; as,-

CE. None whose understanding is limited can be omniscient.

Every man's understanding is limited. RENT. Therefore, no man is omniscient.

CELASTRACEE, se-läs-trai'-se-e, in Bot., the Spindle-CELASTRACEE, se-dis-trati-se-e, in Bot., the Spindle-tree fain, a nat. ord. of dicotyledonous plants in the sub-class Calgriflora, consisting of 30 genera and about 260 species, chiefly natives of the warmer parts of Asia, North America, and Europe, though many are found at the Cape of Good Hope. They are shrubby plants, with simple leaves and small deciduous stipules. Flowers small, regular, and perfect, or rarely unisexual by abortion: sepals and perfect, in phinated in by abortion; sepuls and petals 4-5, imbricated in sestivation; stamens equal in number to, and alternate with the petals, and inserted with them on a large, flat, expanded disk; ovary superior, placentas axile; fruit superior, 2-5-celled. The plants are chiefly remarkable for the presence of an aerid principle. The seeds of some contain oil; those of Celastrus paniculatus yield an oil used as a medicine in India. Two other species of the typical genus, C. scandens and sens-galonsis, have purgative and emetic barks. (See CATHA, ECONYMUS.)

CELERY. (See APIUM.)
CELESTINE, sel'-es-tine, a mineral found in rhomboidal prismatic crystals, consisting of sulphate of strontia. It is the commonest mineral of strontia.

strontia. It is the commonest mineral of strontia. Criestins, self-es-tins, a religious order, founded in the 13th century by Peter de Menron, who was afterwards raised to the papul chair as Celestin V.; whence they took their name. This order speedily extended itself in Italy, France, Germany, and other parts of Europe. Their habit consists of a white gown, a capuche, and a black scapulary. When they go out, they wear a black cowl with the capuche. They are they wear a black cowl with the capuche. They are allowed no animal food except when ill, and have frequent fasts. They rise two hours after midnight to say makins. This order was numerous in the middle

of last century, but it is now nearly extinct.

Chlibacy, sel'-ab-a-se (Lat. cælebs, unmarried), is

the state of wnmarried persons. In the ancient world celibacy was generally viewed with disrespect, and legal enautments were sometimes issued against it. Among the Spartans those who lived in celibacy were subjected to various disadvantages, and in their old age were not treated with the same respect as other citizens. Among the Romans various means were adopted to discourage celibacy, and frequently fines were imposed upon old backelors. Dionysius Halicarnasseus mentions an ancient constitution whereby all persons of full age were compelled to marry; but the first law of this kind of which we have any certainty was that enected under Augustus, called Lex Julia de Maritandis ordinibus, and afterwards Papia-Poppaa, or Julia Papia, from certain amend-ments made on it under the consuls Papius and Popments made on it under the consuls l'apius and l'op-peus. By this law divers percogatives were given to those who had many children, and ponalties im-posed on all that led a single life—as, that they could not succeed to an inheritance except of their nearest relatives, unless they married within 100 days after the death of the testator. The Church of Rome imposes a universal celibacy on all its clergy, from the pope to the lowest deacon and subdeacon. The advocates for this usage pretend that a vow of perpetual celibacy was required in the ancient Church as a condition of ordination even from the carliest apostolic times. This, however, was evidently not the case, for we possess numerous examples to the contrary. It is erally believed that most of the apostles were margenerally believed that most or was, and Philip, one of the even descens was also a married man. St. Paul the seven deacons, was also a married man. St. Paul asserted that he had the power "to lead about a sister, a wife, as well as other spostles" (1 Cor. ix. 5). In

the ages after the apostles, we have accounts of several married bishops, presbyters, and deacons. Polycarp mentions Valens, presbyter of Philippi, who was a married man; and there are still extant two letters of Tertullian, a presbyter of the 2nd century, addressed to his wife. Novatus was a married presbyter of Carthage, as we learn from Cyprian, who was, in the opinion of some, also bimself married; and so was Oscilius, who converted him, and Numidius, another presbyter of Carthage. Many of the ancient fathers, however, wrote in favour of celibacy; and as early as the beginning of the 4th century some persons in the Church advocated the passing of a law obliging the clergy to abstain from marriage. At the council of Nice, A.D. 325, a motion was made to that effect; but it was so strenuously opposed by Paplinntius, an Egypthe was observed by the state of the life court of the 11th century, and even then it was loadly com-plained against by many writers. The old English and Welsh records show that the deergy were married there as late as the 11th century. Celibacy was established in the Greek church by the council of Trullo, 692, but only as regards bishops. Presbyters, deacons, and all the inferior orders, may live in the married state after ordination. Perhaps celibacy more than anything else is to be regarded as the weak point of the Roman Catholic church, and that which contributed most to the success of the Reformation. The violence thus done to human nature was the cause of the gross immorali-ties that prevailed in the Church, and rendered the priesthood the despised among the people. At the time of the Reformation the attention of the Church was directed to this subject, and it was discussed at the council of Trent (1563), whether celibacy ought still to be maintained; but the majority were in its favour. CELLAR, sel'-lür (Lut. cellarium).—A room under a

house or other building used as a repository of liquors

and other stores for a family.
CELLARIUS, or CELLEBARIUS, sel-lai'-re-us (Lat. cellarer), an officer in monasteries to whom belonged the care and procurement of provisions for the convent.

CELLIFFS, sel'-lites, a religious order, founded at Antwerp in the beginning of the 14th century. Their patron was one Alexius, a Roman; and hence, in Italy, they were called Alexians, but in the Netherlands and Germany, where they had many monasteries, Cellites.

CRLLS, sells (Lat. cella, a cell), in Phys., are closed vesicles, or minute bags, formed by a membrane in which no definite structure can be discerned, and having a cavity which may contain matters of variable consistence. These cells, remaining as separate corpuscles in the fluids, and grouped as separate corpuscles in the fluids, and grouped together in the solids, persisting, in some cases, with but little change, in others undergoing a partial or thorough transformation, produce the varieties of form and structure met with in the animal and vegetable textures. The embryo animal, as well as the embryo plant, is, in its early stages, entirely formed of cells of a simple and uniform character; and it is by a gradual transformation in the progress of development that some of these cells become converted into the diversified elements of a complex fabric. We find in the operations of the simple cell an entitone, as find in the operations of the simple cell an epitome, as it were, of those of the highest and most complex plant, which again bear a close resemblance with those that are immediately concerned in the nutrition and trast are influently concerned in the nutrition and reproduction of the animal body. Every cell owes its origin, in some way, to a pre-existing cell. In plants, the most common mode of multiplication is the subdivision of the original cell into two halves. Sometimes the new cells originate in little bud-like prominences on the surface of the parent cell, which, after a time, become detached and form cells. Cells have properly a spheroidal or rounded shape, but they assume va-rious forms from coming in contact with other calls Certain of the animal tissues, in their earlier conditions, appear in form of accongeries of cells, almost entirely resembling the vegetable cells, and in their subsequent transformation pass through a series of changes resembling those that occur in vegetable de-

velopment. In animals, as in plants, there are two principal ways in which cells may be developed; namely, within the cavity of a previously existing cell, in white case the process is said to be endogenous; or in the midst of a plastic fluid, or blastome, probably contain-ing cell-gorms, which has been prepared or elaborated by cell-gorms, but of a previous generation, but which has been set free by their rupture. The nucleus seems to per-form a much more important part in animal than in plant cells, in which, indeed, as a rule, it is absent; and even in animal cells it is often wanting. It is a small round or oval body in the interior of the cell, sometimes lying free, but at other times attached to the cell-wall, and averaging in dismeter, in the spinned cells, from  $\frac{1}{10000}$  to  $\frac{1}{10000}$  of an inch. In the conversion of cells into the several tissues, there is in different instances a great difference, not only in the nature and extent of the change which the cells undergo, but also in the condition which these bodies have attained when the process of change commences. In some cases they have already acquired a distinct cell-wall and cavity; in others they never attain the condition of cells strictly. so called, and the process of transformation begins while they may be said to be but in a nascent state. The following are the principal modes in which cells or their elements are metamorphosed:—1. Increase in size and change of figure; 2. alteration of substance and of contents; 3. division into fibrils; 4. changes in the relation of cells to each other: 5, formation of membranes and fibres from the blastema, without the intervention of actual cells; 6. changes in the nuclei of cells; and 7. ulterior changes in the blastems.
Two or more of the processes here mentioned may occur in the same cell.—Ref. Kölliker's Manual of Human Histology; Von Mohl's Anatomy and Physiology of the Vegetable Cell; Carpenter's Principles of Physiology Carte Control of the Control of the Control of the Carpenter's Principles of Physiology. Physiology; Quain's Anatomy. Cellular Tissue, scl'-lu-lar, in Anat., is the old

name given to what is now commonly known as areolar, reticular, or connective tissue. It is composed of a large number of small transparent fibrils, each about  $\pi_{0\bar{b}_{10}\bar{b}_{10}}$  of an inch diameter, crossing each other in all directions, and leaving small open spaces, or areales; whence its name of arcolar tissue. This is one of the most extensively diffused of all the tissues of the human body, forming the connecting medium of all the others. It is very sparingly supplied with blood-vessels, and no nerves have been found distributed to it.

CELLULAR TISSUE, in Bot. (See TISSUES.)
CELLULARES, sel-u-lä-res, in Bot., plants composed
of cellular tissue only, forming one of the two great
subkingdoms in De Candolle's system of classification.

CELOSIA, se-lo'-si-ii, in Bot., a gen. of plants belonging to the unt. ord. Amaranthacea. Several species have bright-coloured persistent flowers, and are cultivated in our gardens. The best-known is C. cristata, the cock's-comb.

Cher, sell (Lat. cellis, a chisel), in Archeol., is the name given to certain instruments of stone or bronze, used by people in the earliest state of civilization, and found chiefly in tumuli and other early earthworks in Western Europe. The term has been somewhat loosely applied to various kinds of cutting instruments; but it is now generally restricted to chisels or small instruments of a similar character. Some of the stone celts are extremely rude and insartificial, but others are beautifully shaped and highly polished. They vary considerably in size, but are commonly about six inches in length, and generally bear some approximation in shape to an incisor tooth. Bronze celts belong to somewhat higher state of social progress, and present a greater diversity of form than the stone celt. There are numerous examples of both kinds in the British Museum.—Ref. English Cyclopædia—Arts and Sci-

CELTIBERIANS, selt'-i-be'-re-ans, or kelt'-i-be'-ri-ans, & CELTIBERIARS, self-i-be'-re-ins, or kell-i-be'-ri-ins, a people of nucient Spain, who are supposed to have been descended from the Celts of Gaul, who, having immigrated into Spain, became mixed with the native Iberaus; and thus their descendants became distinguished for the best qualities of both peoples. They inhabited a large inland district of Spain, corresponding to the E.W. portion of Aragon, pearly the whole of Chenga and Soria, and a large part of Burgos. They were a brave and warlike people, equally distinguished as cavalry.

## Celtic Architecture

and as foot-soldiers, and proved formidable antago-nists both to the Cartheginians and Romans. They were subdued by Hannibal with difficulty; and, after having submitted to the Romans in the second Punic war, they subsequently revolted against them. It was not till after the wars of Sertorius that they were finally subdued, and began to adopt the Boman language and

CELTIC ARCHITECTURE, self-ik, or kelf-ik.—This term is sometimes applied to the rude attempts at building in stone which were made by the Celts of Gaul and Britain. They consist chiefly of Druidical remains in the form of temples and cromlechs. The temples were huge blocks of stone set up in a circle, in a vertical position, which support others placed horizontally upon them, as imposts or lintels. Some of these stones bear traces of the chisel, and the upright and transverse blocks were often litted together with mortise-and-tenon joints. The cromlechs, which consist externally of a large block supported on three or four smaller ones, were supposed to have been altars on which the Druids sacrificed human and other victims; but they have been found to be monumental records covering cavities below the surface of the earth, in which bones of men and animals, and stone implements, have been discovered. The finest Druidical circles or temples amouvered. The linest Drudgest circles of temples that still remain tolerably perfect are those of Stonehenge and Avebury, in Wiltshire, and of Carnac, near Aursy, in the department of the Morbihan, in the north-west of France. Cromlechs are to be found in many parts of the British isles, the Channel Islands, France, and other parts of Europe. The most remarkable in this country are at Plas Newydd, in Anglesey, and near Aylesford, Kent, the latter of which is known as Kit's Coty House.

CELTIE, celt'-is, in Bot., a gen. of trees belonging CRITE, set-ts, in Dot, a gen. of trees belonging to the Umasee, or Elm order. The fruit of C. occidensalis, which is commonly known as the Sugar-berry or Nettle-tree, has a sweetish, astringent taste, and has been used with some success in dysentery. C. orien-

talis has aromatic properties.

CHLTB, OF KELTS, selts, kelts (Lat. Celtæ; Gr. Keltai, Galatai), an ancient race of people, which at one time appear to have inhabited the greater part of Central and Western Europe. The recent researches of philo-logists have shown that the Celtic language belongs to the Inde-Germanic group; but at what time they migrated westward is unknown. They appear to have been divided into two great families,—the Gauls, who inhabited Gaul, to whom the name of Celts is more properly applied, and the Cimbri, or Cimmerii, who appear to have migrated from Asia at a later period, and spread themselves over Germany to the Ocean. and spread themselves over Germany to the Ocean.
Herodotus, the father of history, mentions the Celts
and Opnete as inhabiting the remotest parts of Europe
towards the setting of the sun, near the sources of
the Danube. A great immigration of the Gauls into
Itsly took place in the reign of the Roman king Tarquinus Priscus, under the leadership of Bellovesus; ammas triscus, under the leadership of Bendeshis, and at the same time another horde of them, under Segovesus, crossed the Rhine, and, advancing as far as the Hercynian forest, settled along the Danube, and in the country now called Bohemia. At a very remote paried the Celtze had also passed into Spain, where their descendants became afterwards known as Celtiberians; and they likewise crossed over into Britain. Several subsequent irruptions of the Gauls took place into Ealy; and in B.C. 390 the city of Rome was taken and burned by these barbarian. About 280 n.c. a vast imilitinde of Celts or Gauls invaded Macedonia and registering of Celes of reason invasion and contains and Crescoe, spreading terror and devastation everywhere before them, and, after making immense booty, returned homewards. An invasion of barbarians from the east of the Rhone and north of the Danube, about the cast of the Rhome and north of the Danube, about 12.0, 113, first made the Romans acquainted with the 12.0, 113, first made the Romans acquainted with the 12.0, 113, first made the Romans acquainted with the 12.0, 113, first made the Romans and Cimbri attacked the Beign; and Comment attacked the Beign; and Comment that the Reign meo, I sleep), denotes hierally a dormitory, or place of comment and Teutones from invading their tentiory. The power of the Celts in Europe was, however, or time decline long before the time of Comment. The Gaula of Italy had been subjugated by the Romans; and in Gaul they were pressed on one side by the Beign and in Gaul they were pressed on one side by the Beign and in Gaul they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in Gaula they were pressed on one side by the Beign and in the control of the Comment o

## Censer

Wales, the Highlands of Scotland, the Isle of Man, and Ireland. The Celtic tongues are the Scotch and Irish Gaslio, the Manx, Welsh, Cornish, and Breton. The Basque, it is now generally agreed, is not a dislect of the Celtic. We know nothing of any original Celtic alphabet, nor of any works in that language; but in Grut they seem to have become acquainted with the Greek language from the colony of Massilia (Marsilles). The Celts were men of large size, fair nomeables. Greek language from the colony of Massilia (Marsilles). The Celts were men of large size, fair complexion, blue eyes, and light-coloured hair. They were of a fickle disposition, warlike, vain, boastful, and clamorous. Their government seems to have been a kind of aristocracy, their chiefs forming a senate or supreme conneil. The Druids formed a powerful body among them, being the guardians and interpreters of their laws, as well as the ministers of their religion. They were also the instructors of the people in all kinds of knowledge with which they were acquainted. Their hards or notes had also creat influence among their bards or poets had also great influence among them, and used to accompany their songs with instrumental music on harps and the like. The Celts had no temples nor images, but worshipped their deity in groves and forests. Their religion seems to have been originally a sort of Theism; but they afterwards adopted some of the gods of the Germans and other natious is undoubted that they offered human victims in their sacrifices .- Ref. Prichard's Eastern Origin of the Cellio Nations, edited by Dr. Latham, 1857; Smith's Die-tionary of Greek and Roman Geography; English Cyclopadia-Arts and Sciences.

CEMENT, se-ment', a term applied to those build-ing materials of a calcareous and silicious nature which, mg materials of a calcareous and smicrons nature which, when mixed with water, set quickly. By this property they are distinguished from mortars, which require time to harden. Natural cements are obtained by calcining srgillaceous limestone containing silicate of alumina. The stone being burnt, the carbonic acid is driven off, and when water is added, a hydrated silicate of lime and alumina is formed. Cements thus made are known in England as Roman cements, and are prepared from the septaria found in the line and London clays. Artificial cements of this character are made by calcining carbonate of lime and fine river mud together. Portland cement is made in this way. Keene's coment is obtained by recalcining gypaum which has been once burnt, and afterwards saturated with alumwater. Parian cement is made in the same way, borax being substituted for alum. Oil cements, consisting of lime, powdered tiles, litharge, and oil, were formerly much used; but they do not stand the London atmosphere, nor have they any powers of resisting force. Temporary cements are used by different workmen for holding their works while in progress. Thus, in lensgrinding, the glass plate is held to the tool by a mixture of resin. beeswax, and whiting. In joining gas-pipes, white or red lead, ground with oil, is used. Electric cement is composed of 1 of beeswax, 5 of resin, and 1 of red ochre. For engineering works, a mixture of two ounces of sal ammoniac, one ounce of sulphur, and sixteen ounces of iron filings is made, and when required for use, it is mixed with twenty parts of iron borings or filings, and made into a paste with water, and applied immediately. A sulphide of iron gradually forms, making the joint as strong as the iron of which the parts are composed. A good coment for mending china is made by mixing fresh plaster of Paris with white of egg and applying it immediately. White lead, carefully applied, also

answers the purpose very well. CREMITATION, se-men-tai'-shun, the process of converting iron into steel by being heated, in the form of bars, for several hours with charcoal-powder in a chest of refractory clay. The result of the operation is called blistered steel, from the appearance of the surface. (See IBON and STEEL, and BLISTERED STEEL.)

censer was a sort of chaffing-dish with or without a censer was a sort of chafing-dish with or without a handle, and probably of various forms. Josephus tells us that King Solomon made 20,000 gold censers for the temple of Jerusalem to offer perfumes in, and 60,000 others to carry fire in. Censers were also much used by the Greeks and Romans, being by the former termed thumisterion, and by the latter thurbulum. They are still used in the service of the Roman Catholic church. Censors, sent'senv (Lat. censee, I take account of), two officers entoug the ancient Romans, first appointed by the stith king of Rome, Servius Tullius. After the abolition of the monarchy, the office of censor was held by the consuls: Special magistrates were ultimately elected: these were all patricians until 351 B.C. when

elected : these were all patricians until 351 B.C., when Caius Marcius, a plebeian, was elected. A decree was afterwards issued, which enacted that one of the was afterware issued, which entered that one of the two censors should always be a plebeian. The duties of the censorship were,—to take the census and register the property of the Roman people; to superintend and watch over the public morality, and administer the public finances. The office was looked upon as the public finances. The office was looked upon as the highest in the state next to the dictatorship, and was originally held for the term of five years, but afterwards only for a year and a half. The decisions of the consors were received with much reverence.

As the regulators of public morality, they exercised absolute powers, which were much dreaded. In time these powers were extended from public investigation to private, and the censors could inflict disgrace on any person whose conduct they disapproved of, either in regard to business or domestic matters. In the regulation of the public treasury they took upon them-selves the collection of all taxes, rates, and tithes; they also prepared the budget or statement of the

CENSORBHIP OF THE PRESS denotes that kind of examination by government officials, to which printed publications are in some countries subjected, previous to their coming before the public. Soon after the invention of printing, the Church became aware of the dangerous character of the mighty power that had sprung up. The priests felt that the diffusion of know-ledge would be destructive of their influence over the people; and hence they exerted all their power against it. They endeavoured first to prohibit the reading, and afterwards they placed restrictions on the printing of books. An ecclesiastical superintendence of the press was introduced in 1470 and 1496; but was more completely established by bull of Leo X, in 1515. In this the bishops and inquisitors were required to cannine all books before they were printed, and thus to prevent the promulgation of heretical opinions. This principle of censorship the Church of Rome still adheres to, and enforces in all countries where she has the power to do so. For the benefit of those countries in which she had not the power to enforce her wishes, indices were prepared of such books as were not to be read under penalty of church censure. The Index read under penaity of church censure. In a macx Librorum prohibitorum was commenced by the council of Trent (1540). For works of an established character which cannot well be prohibited, there is an Index Expurgatorius, denoting that they are only to be read after being corrected or expurgated. In those countries where Protestantism established itself, a censorship of the press was also maintained, but in a more modified form. In England it was the practice to license books form. In England it was the practice to herense books to be printed, the licensing power being chiefly monopolized by the bishops. Hence, we frequently see the word Imprimatur (let it be printed) on old books. It was abolished in this country in 1694, and now any work may be published; but the parties concerned will be amenable to law if it contain anything illegal or libellous. There are different modes of censorship; but the more common are when the MS, has to be subbut the more common are when the MS. has to be submitted to the examination of a public officer or licenser, who deletes any objectionable passages, or when the work is examined after being printed, and found to contain anything objectionable, its sale is prohibited, and the author or publisher liable for prosecution. (See Press, Liberty of The.)

Censers, seri-share, is a judgment condemning some book, action, or person. Ecglesiastical censers is a spiritual punishment inflicted by some ecclesiastical judge, whereby a Christian is deprived of communion with the

the accordatal office. These censures are excommun tion, suspension, and interdict.

CRNSUS, sen'-sus (Lat. census, from censes, I to value, or esteem), denotes an enumeration of people, such as is now made at stated periods in most of the countries of Europe. The practice of numbering the people appears to have prevailed in certain countries from a very early period. We are told that about 600,000 men of Israel went up out of Egypti, besides women and children, and there is reason to believe that they had borrowed the practice from the Egyptians, among whom they had been living. At a later period, David incurred the anger of Jedovah by numbering the people. Joab and the captains of the host were employed to do this work, and it occupied them nine months and twenty days, the number of valiant men in Israel being 800,000, in Judah 500,000. In these early times, the object of numbering the people people, such as is now made at stated periods in i In these early times, the object of numbering the people was chiefly to ascertain the number of fighting men that could be brought into the field; and hence we find that no account is taken of women and children. At a later period, among the Greeks and Romans wealth comes to be regarded as an important principle in the state, and the census was taken more for ascertaining the wealth of the people, in order to adjust the rights duties of citizenship among the different classes. Previous to the time of Solon, a citizen's rights at Athens depended upon his ancestry; but that lawgiver subdepended upon his ancestry; but that lawgiver antituted property for birth, and made a citizen's rights and duties dependent upon his property. Accordingly, all the citizens were divided into four classes, according to their annual income. By the laws of Servins Tullius, the Roman citizens were divided into six classes, according to the amount of their property. The Roman census was taken with great care, and was very minute and full. It indicated not only the number and respective classes of all free persons, but their domestic position as husbands and wives, fathers and mothers, soms and damenters. The census which at first was sons and dauguters. The census, which at first was employed to ascertain the military strength of a people, and afterwards their wealth, may now be said to have in view the much more important object of ascertain-ing, in its widest sense, the social condition and pro-gress of a people, with a view also to finding out those conditions, physical and moral, upon which social pro-gress and well-being depend. It is not a little remark-able, that the first census of this country dates only from the beginning of the present century (1801). Previous to that time, the most vague ideas prevailed as to the amount of its population. Since then a census of the people has been taken decennially, and much valuable information has in this way been collected as to the age, rank, sex, condition, &c., of each person. The last census was taken on 7th April, 1961. and gave the total population of the United Kingdom and gave the total population of the United Kingdom as 29,334,788. A schedule was left at each house on Saturday, 6th April, and called for on Monday, the 8th, to be filled up, with particulars of every person who passed the night of Sunday in the house. No fewer than 44,431 enumerators were employed in distributing and collecting the schedules, besides 4,249 superintending officers, and the Custom-house officers and others employed to enumerate persons in vessels. In other countries, the pariod between the taking of In other countries, the period between the taking of each census varies generally from three to ten years; being three years in Prussia and Austria, five years in France, and ten in the United (?) States of America.

CENT, sent (Lat. centum, a hundred), is a term frequently used in commerce to denote a centum rate or ratio, being so much per hundred. Thus per cent, profit or loss upon a transaction impath that the amount of profit or loss is in the proportion of £5 on every £100. This rate is termed the per-centage. Cent every £100. This rate is termed the per-centage. Cent is also the name of certain small coins in various countries, being the hundredth part of other coins: thus in the United States the cent is the 750 part of sideling, or about one halfpenny English; in France the cent is 750 part of a franc, about 750 for penny English; and in Holland the cent is 150 part of the guilder, or 1 of a penny English; and

(See PRESS, LIBERTY OF THE.)

CRESCER, sen'-share, is a judgment condomning some book, action, or person. Explosure, is a spiritual punishment inflicted by some ecclesiastical judge whereby a Christian ia deprived of communion with the Church, or a clergyman prohibited from exercising that of a man, the lower that of a horse. They are

#### Centaurus

believed to have been skilful borsemen, and the fable probably arose from the man and horse being mistaken for one animal. Their chief occupation was bull-hunt-ing; whence they received their name. They are cele-brated in Greek mythology on account of their war with the Lapithse and their contest with Hercules.

CENTAURUS, sen-tor'-us (Lat., the Centaur), a con-atellation in the southern hemisphere, between those of Lupus and Ara; it contains about thirty-five stars, one

of which is of the first magnitude.

CENTILOQUIUM, sen-ti-lo'-kwi-um (Lat.), is a term applied to collections of one hundred sentences or sayings; as the Centiloquium of Hermes, containing one hundred aphorisms or astrological sentences talsely ascribed to HermesTriemegistus, and the Ceutiloquium

of Ptolemy, a famous astrological work.

CENTIFER, sen'-to-pede (Lat. centum, a hundred; pedes, feet), (Scolopendru), a gon of carnivorous Annulose, distinguished by possessing antennes of four-teen joints or upwards; a mouth composed of two mandibles, a quadrifid lip, two palpi or small feet, united at their base, and a second lip formed by a second pair of dilated feet joined at their origin, and terminated by a strong hook, having an opening beneath its point, through which a strong poison is rjected. In the West-India islands and the hetter parts of America the centipede is regarded very seriously as a pest. They attain a length of five or six inches, and very frequently find their way into beds. They will endearour to escape when a light is brought into the room, but, if molested, will turn and bite, the bite immediately producing inflammation and fever. The common English centipede, however, is a harmless thing, not exceeding an inch in length, and for the most part hiding under the decayed bark of trees and among old lumber.

CENTO, sen'-to (Gr. kentron, a thing of patches), is a literary composition formed of verses or passages from one or more authors, disposed in a different order, and arranged so as to bring out a different meaning. Considerable dexterity was frequently displayed in the combining of passages of different authors so as to form a regular and connecting whole. Thus there were in early times Homero-centones and Centones Virgiliani. It was also a fuvourite amusement in the

Middle Ages.

300

CENTRAL CRIMINAL COURT, sen'-tral, a court established in 1834 for the purpose of trying cases of treason, murder, felony, and misdemeanour committed within the city of London, the county of Middiesez, and parts of Essex, Kent, and Surrey. It is also authorized to try offences committed on the high seas and other places within the jurisdiction of the Admiralty of England. The court of Queen's Bonch may also order a certain class of offenders to be tried here. The area over which the jurisdiction of the Central Criminal Court extends is nearly one bundred and thirtieth part of the area of England and Wales; but the proportion of population is only one-seventh, when compared with that of England and Wales. The district included in the jurisdiction, and mentioned above, is, for all purposes under the act by which it was established, considered as one county, and in all indictments and presentments the venue rans, "Central Criminal Court to wit." The judges rans, "Central Criminal Court to wit." The judges may be selected from a very extensive list. They may insist of any two or more of the following persons: the lord mayor of the city of London for the time being, the lord chancellor, the lord keeper of the great seal, and all the judges of her majesty's courts of Queen's Banch, Common Pleas, and Exchequer, for The time being; the chief judge and the two others in Bankraptcy, the judge of the Admiralty, the dean of the Arches, the aldermen of the city of London, the recorder, the common serjeant, the judges for the time being of the Sheriff's Court of the city of London, and being of the Sheriff's Court of the city of London, and sany person or persons who hath, or shall have been lord chancellor, lord keeper of the great seal, or a judge of any of her majesty's superior courts at Westminster; together with such others as her majesty, her heirs and successors, shall from time to time name and appoint by any general commission. On account of the extent of this int, it is found unnecessary to issue a commission every time the sessions are held; and the period of holding the sessions is not interrupted 474

#### Centring

when the judges of the Westminster courts are on cir-cuit. At the Old Bailey, and the New Court adjoining, the sessions are held twelve times a year, and the judges generally selected are two common-law judges and the recorder of the city of London. The sheriffs of the city of London and of the counties of Middlesex, Essex, kent, and Surrey, susanon the jurors according to the district in which they live. Jurors from Essex, Kent, and Surrey, who have served upon any jury at this court, are exempt, during the ensuing welve months, from serving upon any jury in any court held in the county in which they reside, except the sessions of the

CENTRAL FORCES are those forces which cause body in motion to tend towards or recede from the centre of motion. The first law of motion is, that a body must continue for ever in a state of rest, or in a state of uniform and rectilineal motion, if it be not disturbed by the action of an external cause. Upon this law the doctrine of central forces is founded. It therefore considers the external forces which act upon a body in motion when there is an alteration either in its velocity or direction round a central point. It also considers the law of the force by which a body moves round another in a known curve, and solves various mathematical problems. Gravity, as exemplified in the force which acts on all bodies from the centre of the earth, is the simplest and most general example of a central force. Kepler and Newton gave much time and labour to the study of central forces.

CENTEALIZATION, sen-trall'-i-sai-shun (Gr. kentren, a point, the centre), denotes generally the bringing or reducing to a centre or within small compass, and is frequently applied in politics to the tendency to bring together all the departments of state administration to one centre,-to remove all local offices to the capital.

CENTRE OF GRAVITY, sen'-ter, a term employed to denote a certain point in the interior of a body, or system of bodies rigidly and invariably connected, so situated that any plane whatever which passes through it divides the body into two segments of equal weight.

CENTER OF GYRATION is that point in a rotating body, or system of bodies, at which, if the whole mass were collected, a given force applied would produce the same angular velocity that it would have commu-nicated to the system in its first condition.

CENTER OF MAGNITUDE OF FIGURE is that point in plane figures and curved surfaces where, supposing their areas had weight, they would balance themselves. Thus, the centre of magnitude of a circle would be its own centre. The same term is applied to any point which bisects all lines that pass through it, and are terminated by the circumference

CENTRE OF OSCILLATION is that point in a body oscillating about a fixed axis, into which, if the whole mass were collected, the body would vibrate through a given angle in the same time as in its first condition.

CENTRE OF PERCESSION is that point in a solid body. r system of bodies, into which, if the whole mass were collected, the greatest possible effect could be produced by striking it against another body. It may also be defined as a point in the axis of a moving body at which, when striking an immorable obstacle, the body rests in equilibrio, without inclining to either side or acting on the centre or axis of suspension.

CENTER OF PRESSURE of a fluid pressing against a surface, is that point at which, if a force equal to the pressure were applied in an opposite direction, the sur-

face would remain at rest.

CENTRIFUGAL FORCE, sen-triff-u-gil (Gr. kentron, centre; Lat. fraio, I see), is the force that urges a revolving body to fly off in a straight line instead of describing a curve. The moon is held in her orbit round the earth by centripetal force, and a stone flies from a sling by centrifugal force.

CENTRING, OF CENTERING, sen'-tring (Gr. kentron, the centre, a point), a term used to denote the frame-work on which the bricks or stones that are used to form an arch or vaulted roof are supported during the process of construction. For small arches, such so those of doors and windows, it simply consists of two boards cut to the required shape, and kept spart by slips nailed to the edge of each, which correspond in slips nailed to the edge on each, which correspond in length to the thickness of the wall in which the arch is placed; but for bridges with arches of great span and

## Centripetal Force

breadth, a more elaborate system of framework is required, which must be put together in such a manner that it will offer a sufficient resistance to the weight placed upon it without bending perceptibly beneath it, and that it may be readily taken away when the architecture when the same to account the contract of the state of the same to account the same transfer of the same transfer is completed, care being taken to avoid giving heavy blows in removing it, which may shake and injure the fresh masonry. (See BRIDGE.) In building arches of brickwork or small stones, the trames are placed five or ornework or small stones, the trames are placed five or six feet apart, and tied together with braces, and on these thick narrow planks are placed, fitting closely together to support the bricks; but when large stones are used, close boarding is not required, and they are supported on what are technically called "laggings." When the span is of great size, the centering consists of a great number of vertical frames or trusses, disor a great number of vertical range of a tusta, us-posed in such a manner as to offer effectual resistance to the strain that is brought to bear on them in the direction of their length; and these frames are strengthened with horizontal beams and cross braces, the whole forming a rigid network of timber. making frames for centerings, it must be carefully contrived that the load shall not act in a direction transverse to the grain of the wood that is used; the pressure must, therefore, he carried throughout the length of the beams, some of which, in the usual method construction, are directed against the abutments which are to support the arch, and sustained by them, and others which tend in an inward direction, towards the centre, are supported and prevented from yielding by the longitudinal pull of other beams that cross them obliquely. Shoes of cast-iron, that receive the ends of the beams, are used in modern centerings to obviate the necessity of making tie-joints, which weaken the beams. Care must be taken to prevent the centering from rising at the crown, which it is liable to do if it be not skilfully made, on account of the weight of the haunches of the arch tending to push the crown upwards. The centering used for Waterloo bridge, designed by Rennie, is one of the best examples in which the frames are supported by the abutments only. In building Chester and Gloucester bridges, Mr. Harrison, the engineer of the former, supported his centering on temporary piers built in the bed of the river; while Telford, who built the latter, supported his on piles. Flexible centres, so called because the timbers of which they are composed can move freely on one another, are seldom used in the present day, because they invariably rise at the crown from the weight of the they invariantly use at the crown from the weight of the haunches, and the regularity of the curvature of the arches cannot be relied on. The arches of the beautiful elliptical bridge of Neuilly, built by Peyronnet, were constructed on centerings of this description.

CENTHIPETAL FORCE, sen-trip-e-tät (Gr. kentron, centre; Lat. peto, I seek), is the force by which a body in motion is kept revolving round a central point, in-

etead of flying off at a tangeut to its orbit. CENTUARY. (See ERYTHERA, SABBATI. (See ERYTHERA, SABBATIA.)

CENTUALIS OF MACHINEUR, sen'-tu-recs, the name of the first great Protestant history of the Church, and is so called from being divided into centuries, each volume taking up 100 years, and from Magdeone volume taking up 100 years, and from auguer-burg, the city where it was prepented. It was prejected by Matthias Flacius, about 1552, and the first volume was published at Bale in 1559. Thirteen volumes have appeared, bringing the history down to 1300. It is a work characterized by great judgment, learning, and fidality. Each confurer is treated under sixteen and fidelity. Each century is treated under sixteen distinct heads or chapters, viz.:—1. General View of the Period; 2. Extent and Propagation of the Church; 3. Persecution and Tranquillity of the Church; 4 Doctrine; 5. Heresies; 6. Rites and Ceremonies; 7 Government; 8. Schisms; 9. Councils; 10. Lives of Bishops and Doctors; 11. Heretics; 12. Martyrs; 13. Miracles; 14. Condition of the Jews; 15. other Reli-gions; 16. Political Condition of the World. In the preparation of the work there were five general directors and ten paid agents, seven of whom, well-informed students, were employed in collecting materials; two of greater learning and experience arranged the mat-ter thus collected, and submitted it to the directors

### Cerasus

Cinchonarea. The annulated root of C. treasmanhs is the officinal presecuants of the British pharmacopoiss. It is known as true, assaulated, Brasilian, or Lisbon ipecacuants, and is the only sort cons monly met with in this country. It is collected in all seasons of the year, but chiefly from January to March, and is imported from Rio Janeiro, Bahia, and Pernambuco. When given in large dose, it acts as an emetic and as a purgative: in small doses it is expectorant and diaphoretic. Its peculiar properties are principally due to an alkaloid called emetima.

CRPHALASPIS, sef-ü-lüs'-pis (Gr. kephale, head, aspis, shield), in Geol., the Buckler-head, a fish of the lower Old Red Sandstone or Devonian period, so called from having the bones of the head united into a single shield-

like case.

CEPHALIC, se-fall-ik (Gr. kephalikos), is applied to something pertaining to the head. Thus, cophalic medicines are such as are administered for disorders of the head.

CEPHALITIS, sef-ä-li'-tis (from Gr. kephale, the head), in Med., inflammation of the brain. (See BRAIN,

DISEASES OF THE.)

CKPHALOPODA, sef-d-lop'-s-dd (Gr. kephale, head; pons, foot), a class of molluscous animals, more highly organized than any other, presenting undoubted rudinents of an internal skeleton, and containing secretive, digestive, respiratory, and generative organs. They are also distinguished by the possession of locomotive organs around the head in the shape of prolonged tentacula, which project forward and more or less conceal the mouth.

CREHLUS, se'-fe-us, a constellation of the northern hemisphere, midway between the Polar star and Cyg-nus. The principal stars in this group are of the third magnitude only.

CEPI CORPUS, sc'-pi kor-pus, is a return made by a sheriff upon a capias, or other process to like purpose, that he hath taken the body of the party named in the process, as he was thereby commanded.

CEPOLA, sep-o'-ld, a gen. of fish, the bodies of which are much compressed and clongated.

CERAMBYCIDE, se-ram-bit-se-de, a family of coleopterous insects, distinguished by the inordinate length of their antenne. Generally they are of elegant form, and are found in forests and woods, on the trunks of trees, but rarely on flowers. Some of the exotic species are remarkable for emitting after death a scent something like attar of roses. The only scented Cerambyeid known in England is the musk-beetle (Cerambyx moschatus). It is about an inch long, and of a fine green colour. It is found on willows in the neighbourhood of London. There is a very splendid collection of these insects in the British Museum.

CERASTES, se-rāz'-less (Gr. kerastes, horn), a snake distinguished by two horny protuberances on its head, and hence known as the borned snake. It is said to exist almost entirely without water. It is found in

Libya, Arabia, &c.

CERASUS, ser'-d-sus, in Bot., a gen. of trees be-longing to the nat. ord. Rosacce, sub-ord. Amygdales. Several species or varieties of this genus produce the well-known fruits called cherries. The varieties usually cultivated in our gardens are supposed to have been derived originally from two wild species, C. avium and vulgaris. Both have white flowers in clusters or nearly sessile umbels, and both are generally regarded as natives of Britain and of the middle and south of Europe. The timber of C. avium is valuable for the purposes of the cabinet-maker, turner, and musical instrument maker; the straight small branches are used for making pipe-stems, and the leaves have been used as a substitute for tea. The bark of the species C. capallin possesses astringent and febrifugal proper-ties; that stripped from its root is used in Mexico as a remedy against dysentery. The leaves of C. capri-cids contain so much hydrocyanic (prussio) acid as to prove poisonous to cattle that feed upon them. Most parts of the species C. Lauro-carasus, the cherry-laurel, Most but especially the leaves and seeds, are poisonous. The in copy of the whole.

Carnains, sef-a-e-lis (from Gr. kephale, head), the leaves evolve a variour which is destructible to the Bot., a gen. of plants belonging to the nat. ord. insect life: hence some gardeners make use of these states.

leaves for killing blight. Cherry laurel water, obtained leaves for killing ought. Oberry-leaves water, to use the distilling the leaves with water, is used medicinally for similar purposes as hydrocyanic acid. The plant is common in our gardens, and is popularly known as the "saurel," though it is not a member of the true laurel family. The kernels of the species C, occidentalis, a native of the West Indies, and others, are used to the west indies, and others, are used. its, a native or the west and the succes, and concern the purpose of flavouring liqueurs, such as cherry-brandy, Kirschenwasser, Maraschino, and Noyeau. The species C. Padus, or bird-cherry, has similar properties, though less powerful, to those of the cherriaurel. Q. sirginiana, the choke-cherry, has astringent and febrifugal properties, and its fruits are commenly raixed with penumican in North America. C. scrotina, the wide or black cherry of the western states of America, is a beautiful and useful tree. The cherries are sometimes eaten, but are not very palatable. The wood is esteemed by cabinet-makers, having a close grain, and taking a very high polish. The inner bark forms and taking a very high polish. The inner bark forms prescribed of late in America, and which is just beginming to receive the attention of European practitioners. It is used as a tonic instead of cinchons, and as a sedative for the alleviation of general and local irritation. It is taken from any part of the tree, but preferably from the root. It has a lively einnamon-colour, and. when fresh, a characteristic odour, like that of bitter almonds.

CHRATIN, se'-rd-tin (from cerasus, the scientific name of the cherry-tree), the portion of the gum of the cherry-tree which is insoluble in cold water.

CERATONIA, ser-à-to'-ni-a, in Bot., a gen. of leguminous plants of the sub-ord. Cesalpiniez. The most important species is C. sitiqua, the ripe fruit of which is known under the names of carob, locust, St. John's bread, and Algaroba bean. Its pulp has a very sweet taste, and is supposed to have been the food of St. John the control of the control of

taste, and is supposed to have been the food of St. John in the wilderness. The fruit is now largely imported into this country for making cattle-food.

CERITOPHYLLACEE, se-rā-to-fil-lai'-se-e, in Bot., the Hornwort fam., a nat. ord. of dicotyledonous plants in the sub-class Monuchlamydee. There is but one gen., Ceratophyllum, the species of which are aquatic herbs, with verticillate leaves and minute monoccious of the post part of the post part of the protection of the post part of the protection of the post part of the post part of the protection of the post part of the protection of the post part of the protection of the protection of the post part of the protection flowers, natives of the northern hemisphere. properties and uses are unknown.

CERDON, ser don, an ancient sect of heretics, so called from one Cerdon, who flourished at Rome about A.D. 140.

CEREBELLUM. (See BRAIN.)

CREERIC ACID, ser-e-brik (Lat. cerebrum, brain), an soid of a peculiar character found in the brain of animals, partly uncombined, and partly in the form of cerebrate of sods. It is a white solid, of a fatty nature, and may be obtained in crystalline grains, which are coluble in boiling alcohol and ether, but insoluble in cold ether. It is insoluble in water, but swells up when left in that liquid for several hours. This acid was formerly called Cerebrin. The component parts of cerebric acid are in 100 parts :-

Carbon	66.7
Hydrogen	10 6
Nitrogen	2.3
Oxygen	
Phosphorus	0.9
	100.0

CEREM, se'-rem (Lat. cera, wax), a solid waxy body obtained from beeswax, which is supposed to be identical with parafilm.

CEEEMERTS, eere'-ments (Lat. cera, wax), were clothe dipped in melted wax, with which dead bodies were cafolded when they were embalmed.

Chermonies, Mastre of the source instituted by James I. to attend to the proper presentation of ambassadors, and other persons of quality, to the sovereign. The gentleman filling this office is necessarily a person of good address and master of several languages. He attends at court on all occasions of state ceremonial, and has under him an assistant master, or deputy.

CERRMONY, ser'-e-ma-ne (Fr. córémonie; Lat. care-

monia), is applied to certa n forms or rites by which an act is rendered more grand or impressive. Ceremonies may be said to be of four kinds:—1. social; 2. sucred;

3. state; 4. international. Social ceremonies will be noticed under Errqueite, and state ceremonies under such heads as Coronation, Presentation, Opening OF PARLIAMENT, &c. Sadred reremonies are defined to be "the external rites and manner in which the ministers of religion perform their sacred functions." In respect of ceremonies there is a very marked difference be-tween the old dispensation and the new. The former, or Mosaic dispensation, abounds with rites and cere-monies; the latter, or Gospel dispensation, is remark-able for the want of them. In what may be termed the childhood of the human race, numerous stringent luws and regulations are laid down for their guidance, and sensual representations are employed to make a deeper Under and more lasting impression upon the mind. the Christian economy, when men may be said to have been set free from a state of pupilage, his mode of worshipping the Creator was left very much to himself, and he was taught to seek within himself for those directions by which he might best attain a holy life and fulfil his high destiny. The great gospel law laid down on this subject was, "Let each be persuaded in his own mind, and so let him act." How far rites and ceremonies of human appointment may be employed in the worship of God is a very important question, and one which has given rise to much discussion. Of the two great sections of the Christian church, the Roman Catholic and the Protestant, the one is characterized by its attachment to, the other by its rejection of, human rites. One great peculiarity of the Christian religion is its striking adaptation to fallen human nature. Its laws are founded upon the necessities of our nature. The highest said purest worship of God is undoubtedly that of the heart; but in man's present infirm and imperfect condition, the heart may be greatly influenced by the senses; and hence the proper object of all religious rites and ceremonies is to mpress and elevate the heart through the feelings. All religion must in some measure be dependent upon external forms; and so high an anthority as St. Augustine declares that "no religion, either true or false, can subsist without some ceremonies." The great difficulty is to determine the length to which it is proper to go in accommodating religious ceremonies to weak human nature. When, from being a means of worship, they come to be regarded as worship itself, they are worse than useless, they are permittous. The Roman Catholics may have gone too far in this direction; but the majority of Protestants seem to have fallen into the other extreme, and to pay too little regard to the externals of religion. But we believe that no general rule can be laid down on this subject, outward rites and ceremonies being much more necessary to some than others. The great rule is for each to be persuaded ir his own mind as to what is best for him, and to act accordingly. It has been frequently remarked that there is a striking similarity between many of the Jewish ceremonies and those of the ancient Egyptians; and many have been of opinion that Moses adopted many of them from the Egyptians. This may probably have been the case; and we are also told that many things were permitted to them, on account of the hardness of their hearts. There can be no doubt that many of the cremonies of the Church of Rome were borrowed from the heathens. International ceremony.—Among independent states there exists a sort of international etiquette, according to which certain marks of respect are shown to the states, their rulers or representatives, by other states, and a certain rank or dignity accorded to them. In Europe, in the Middle Ages, frequent disputes took place among the rulers or representatives of the different states, on the subject of precedence. Claims for precedence were advanced on various grounds; as on the form of government, the number of crowns, the titles, achievements, extent of possessions, antiquity of their family, or the length of time that Christianity had been established in their dominions. At the congress of Vienns, issued in their dominions. At the congress of vienns, the question of rank among the different powers was discussed, and a commission appointed with the view of settling it; but as no agreement could be come to, the matter was allowed to drop. Rulers of equal dignity, when they make visits, concede to each other the precedence at home; at other times they travel incognition of dependence of the control of th nito, or do not appear on public occasions, or do so

Chros

Cession

with a reservation respecting their dignity. Emperors and kings style each other "brother," while they call princes of less degree "cousin." To international ceranonies belong—1. Titles of rulers; 2. acknowledgment of the title and rank of rulers; and 3. marks of respect conformable to their rank and title.

CREES, se'rees, one of the asteroids that revolve between the orbits of Mars and Jupiter. It is the first of this group of minor planets in order of discovery, and the largest of them, with the exception of Vesta. It was first observed by Pinzzi, an Italian astronomer, at the observatory at Palermo, in Sicily, January 1, 1801. The elements of its orbit were calculated by Gauss. It derives its name from Ceres, a heathen goddess that derives its name from Ceres, a heathen goddess that was the object of especial worship in Sicily.

CERINTHIAMS, se-rin'-thi-ans, the followers of Cerinthiams, were among the earliest of the sects of heretics that sprang up in the Christian church, Cerinthus, according to some, was a contemporary of the apostic John; according to others, he lived in the 2nd century. He was a Jew, and studied philosophy at Alexandria; but the greater part of his life was spent in Asia Minor, where he promulgated his heretical doctrines. What the exact nature of these were it is difficult to say, for the accounts given of them are various and contradictory; but they seem to have much resembled, if they were not identical with those of the Gnostics. (See GNOSTICS.)

CRIUM, se'-ri-um, symbol Cc, equivalent 47, a very rare metal, existing in allanite, cerite, and cerine. It is only known as a grey powder, which becomes lus-trous on being burnished. It forms two oxides,—the protoxide and peroxide, which form a few salts of no importance or interest. They are said by Rumnels-berg to be isomorphous with those of cadmium.

CERCLEIN, ser-o-leen, a greasy body found in beeswax, to which its colour, odour, and tenseity are due. It has an acid reaction, and fuses at 83°. It is soluble in ether, and is but imperfectly known. It is obtained by macerating the wax in cold alcohol, which retains it in solution.

CEROTIC ACID, esr-ot'-ik, an acid contained in varying quantities in beeswax. It is obtained by dissolving the wax in hot alcohol and crystallizing. Genuine beeswax contains about 22 per cent. of cerotic acid. Heated with potash, it produces cerotate of potash and

ceroic alcohol.

Chroxylon, scr-ox'-e-lon, in Bot., a gen. of palms. The species C. audicola yields wax, which is applied to many useful purposes. It is a native of South America.

CERTAINTY, CERTITUDE, ser'-tain-te (Lat. certum, from cerno, I perceive), is applied primarily to the state of a person's mind when he feels sure or convinced of anything; but is also applied to the truths or events respecting which this conviction may be entertained. Certainty is *physical* when it is according to the laws of nature; *moral* when in accordance with the common order of things and the received opinions of mankind; and metaphysical when springing from intuitive beliefs, as the first principles of natural law. According to the mode in which it is attained, certainty is immediate when by sense or intuition, or mediate when by reason and demonstration. Some philosophers have made sense the measure and ground of certainty; others reason; and others, as Descartes, self-consciousness.

CERTIFICATE, ser-tif'-e-kait (Fr. certificat, from Low Lat. certus, certain; facto, I make), a testimony in writing as to the truth of a fact, or number of facts. writing as to the truth of a fact, or number of facts. Certificates, for a variety of purposes, are recognized by the law of England. Among these may be mentioned,—the annual certificates of attorneys (see ATTORNEY); a bankrupt's certificate of conformity; the certificate of appointment to a bankrupt's estate and effects, granted to the creditors' assignees; the certificate of counsel, in order to enable a client to litigate in forma pauperis; the certificates of the judges belouging to the higher common-law courts at Westminster, ing to the migher common-law courts at Westminster, granted for various purposes; and the certificate of the registry of a ship granted by the collector, compttoller, or principal officer of the custom-house at the port of registry. This last certificate is held by the captain as a voucher of the character and privileges of his ship as Battish years. his ship as a British vessel.

CERTIORARI, ser'-ti-o-rai'-ri (Low Latin, certioro),

is a writ issued out of the court of Chan-a superior court of the common law, dirthe queen's name to the judges or officers of infe the queen's name to the judges or officers of sistence courts of record, commanding them to return the record of a cause or matter depending before them, to the end that the party may have the mine sume and speedy justice. It may be had either in ordinal or civil cases, unless it be taken away by the express words of some set of parliament, which is very frequently the case where the statute gives jurisdiction to justices of the peace over criminal offences, and in other matters. In criminal cases the court of Queen's Bench has a superinandance over all infestions. Bench has a superintendence over all inferior courts, and may remove the indictments or other proceedings therein depending, and transfer them to its own jur diction. The object of the writ is to obtain relief from some inconvenience supposed in the particular case to arise from a cause being allowed to proceed to trial before an inferior jurisdiction, less capable than the superior court of rendering complete and effectual justice, or to quash the orders or proceedings of such inferior jurisdiction. The most usual instances in which the writ is granted in criminal cases are,—1. To consider and determine the validity of indictments and the proceedings thereon, and the finding or verdict of a jury on coroners' inquisitions, and to quash or confirm them as there is cause. 2. Where it is surmised that a partial or insufficient trial will probably be had in the court below, the indictment is re-moved, in order to have the prisoner or defendant tried at the bar of the Queen's Bench or before the justices at Nisi Prius, or at the assizes: 3, in order to plead the royal parcon; 4 to issue process of out-lawry against the offender in those counties or places where the process of the inferior courts will not reach him; 5. to remove orders of justices in quarter or petty sessions, for the purpose of having them quasiled. It is also issued when peers are indicted for treason or felony, or for misprision of either, but not for any other offence. Under the writ the indictment is removed into the court of the Lord High Steward of Great Britain, in order that the defendant may be tried by brish, in order that the detendant may be tried by his peers. A certiorari to remove an indictment may be granted at the instance of either the prosecutor or defendant; but before it be granted to say person (except the attorney-general), the application for it must be by motion made in the Queen's Bench, or before a superior of the control of the c before some judge of the court; and where the appli-cation is made by a defendant, he must, before the writ is issued, enter into a recognizance before a judge of the Queen's Bench, or a justice of the peace, in such sum and with such sureties as the court or a judge may direct, to defend the indictment, and appear to receive

judgment if he be found guilty. CEBUSE. (See LEAD, CARBONATE OF.)

CERVIDE, ser-vi-de (Lat. cervus, a deer), the Stag

CENVIDE, ser\*-vi-de (Lat. cerus, a deer), the Stag or Deer class of animals, a gen. of quadrupeds belonging to the order Pecora. The generic character is solid horns, covered, while young, with a hairy skin growing from the top, naked, anumal, and branched. There are several species of the Cervidæ. (See Deer.) Cressavit, ser-sai\*-vil (Lat., he hath ceased), was a writ which anciently lay by the statutes of Gloucester and Westminster 2. When a man holding lands of a lord by a rent or other services, neglected or ceased to perform his services for two years together, or where a religious house held lands given to it on condition of performing some certain spiritual service, as dition of performing some certain spiritual service, as reading prayers or giving alms, and neglected it,—in either of which cases, if the cesser or neglect had continued for two years, the lord or donor, and his heirs, should have a writ of cessanit to recover the land itself; eo quod tenens in faciendis servitiis per biennium iam cessavit.

CESSIO BONORUM, ses'-si-o bon-o'-rum (Lat., cession of goods), in Scots law is a process by which an insolvent surrenders his property for behoof of his creditors, and is, in consequence, set free from prison or obtains pro-tection. The insolvent, however, is not, as in seques-tration, discharged from his debts, for which his goods may be again attached at any future time; his person only is protected from any future proceedings for past

CRESTON, seek'-un, in Eccl. matters, is applied to the voidance of a benefice or dignity in the church, arising

#### Cestui que Trust

from the accepting of another, which is by law incompatible with it. This voidance takes place, ipeo facto, upon the acceptance of the second benefice, and the patron may at once, without any express resignation present a new incombent and require his admission.

CESSUI QUE TRUET, set -b-ke-trust', is the person for whose benefit a passive, or active, or special trust is designed, and reposed in some other person to execute, and his interest is described as a trust estate; which distinguishes it from a use on the one hand, and from lead setate on the other (See Turst).

from legal estate on the other. (See Tausr.)
Castur Qua Uass is one who has the beneficial ownerstip or me of land, the legal seisin or feudal tenancy
of which is in another, either by express declaration or
deed, or by implication, from the nature of the conversame titled! (See Uass.)

veyance itself. (See Usns.)
OBSTUL QUE VIE, set'-a-ke-ve, is one for whose life

any lands or tenements are granted.

Observe, see'-tue (Gr. kealos, embroidered), a fine embroidered girdle worn by the Greek and Roman women close under the breasts. It was distinct from the sone, which was worn round the loins. Homer asserbes the power of charming and conciliating love to the cestus of Venus, which was covered with alturing representations. When Juno wished to gain the love of Jupiter, she borrowed this girdle from Venus. The cestus, or certus, was also the name of a samplet worn by the Roman purilists. (See Chartes)

gauntiet worn by the Roman pugllists. (See Castus.) Charges, se-tai-se-a (Gr. ketos, Lat.cetos, a whale), an order of the mammalia, which differs from the rest of that class both in form and habits. In ordinary language it is generally classed with the fishes. All the ectacea have a fish-like form; but the tail fin is horizontal, and not vertical, as in fishes. It is moved by very powerful muscles, and is the great instrument of progression. There are no posterior limbs, and even the pelvis is only represented by two small rudimentary bones. The auterior limbs are in nearly all cases adapted for swimmings. The hones, however, in the ekseleton appear like those of a hand, but much abbreviated and solidified. The head is joined to the body without any apparent neck, and the upper parts of the rertebre are ankylosed or consolidated. The skin is naked, and some of the species are conspicuously whiskered. The cetacea are viviparous, and suckle their young, towards which they show great affection. They are warm-blooded, and breathe by lungs, and whale first at the surface of the water. (See Greenland)

Catragella, setrai-re-a, in Bot., a gen. of lichens, which includes the well-known Lecland moss. This lichen, which has been named C. islandiza, is officinal in the British pharmacopens, and is employed both as a nutritions food and as a mild mucliaginous tonic in catarrh and consumption. Combined with cocoa, it forms the article known as Iceland-moss cocoa, which was originally prepared by Mr. Dunn of London. Two kinds of starch are found in this lichen,—one called lichen starch, and the other inulin; also n peculiar bitter principle, which has been named cetrarin. When used for food only, the plant should be deprived of its bitterness, either by heating it twice in water to near the botting-point, or by digesting it in a weak alkaline solution, formed by adding half an onnee of carbonate of potash to about a gailon of cold water, and afterwards washing it with pure water. The species C. simulis possesses somewhat similar properties.

CEVADILLA. (See ASAGREA.)

CETLON MOSS. (See GRACILABIA.)

CHAPP- or CHAPP-WAX, tchafe'-waks, was an officer in changery who fitted the wax for the scoling of the write and such other instruments as were delivered out under the great seal, or seal of the court.

CHAPP-CUTTER, tchaff-kut-ter (Sax. ceaf, chaff; Nor.

Charm-Curren, tendy-kut-for (Sax. ccal, chair; Norcore, cut), an implement used by farmers for cutting hay and straw into small lengths. Much ingenuity has been applied to the construction of these machines, which are principally intended for the prevention of waste in feeding animals.

Charrimon, tolay fact (Fringilla calebs), one of the foot of the tree containing the bold free bird, the most popular of European song-birds. Not only in England is the chaffinch a favourite,—with the birdcatcher places his decoy, covering it overcage, handkerchief, and al—with a handful of grass. Then he is a honsehold proverb; and as among us like the birdcatcher blaces his decoy, covering it overcage, handkerchief, and al—with a handful of grass. Then he sticks the little branch on which the scaled bird is mounted into the trunk of the tree, and just with them they are said to be "gay as a challingh." above it, and at a slight angle, one or two of the

#### Chaffineb

Nowhere, however, is chaffinch enthusiasm carried to so high a pitch as in Germany. Bedestien informs us that in the kuife-making village of Ruhl the inhabitants are such great chaffinch-fanciers that they will go sixare such great challingly-language that they will go six-teen miles to catch a bird, and that on one occasion, when a peculiarly good one was in the market, a crasy fancier, whose means were at low ebb, went and sold his only cow, and bought the coveted chaffinch with the money. The plumage of the chaffinch is as fol-lows:—Fore part of the head black; back part, and extending even to the nape of the neck, blue, shading off to an olive-tinted chestnut, and again to a greygreen to the stump of the tail. and grey, and on each of the two outer feathers there is a peculiar wedge-shaped white spot. From the root of the lower half of the beak to the extremity of the under part of the body the colour is reddish-chestrut. The male may be distinguished from the circumstance of being smaller than its mate, whose length is six inches, and from the latter's under parts being dingier. chaffinch lays four or five eggs, of pale purplish-buff colour, sparingly streaked and spotted with reddish-brown. Insects are its chief food, and in the summer season it effects incalculable good by destroying myriads of aphides and caterpillars. In Italy the chaffinch is killed for the table. It is very widely spread, being found in parts of Asia, in the north of Africa, and as

HEAD OF CHAFFINGE.

far west as the Azores. The chaffinch is a very pugna-cious bird, and it is of this, its failing, that the English birdeatcher takes advantage in the profitable sport known as "pegging." First of all, the eatcher must be provided with a chaffinch that will sing loud and fearlessly in the dark and when its cage is in motion. This is effected by allowing it to remain in its dark moulting-box after the process of moulting is com-pleted, and placing in the same apartment an able singer of its own species. After a while the little prisoner will sing as cheerily as its tutor. Then its by an elastic cord. Although the consequent swinging metion seems to bother it vastly for a day or two, it grows used to it in a wonderfully short space of time, and will sing screnely with its house rocking like a ship at sea. Then its cage is tied in a handkerchief, and its trainer walks about the chamber with it swing ing in one hand; and so the teaching progresses, until the poor bird will set up its little pipes at any hour and almost in any position; then it is called a "pegging-finch," and is worth from one guinea to five. Besides one of these decays, the chaffinch-pegger must have a stuffed chaffinch mounted on a forked stick, and some pieces of whalebone furnished with a spike in one end, and thickly smeared with birdline. Thus equipped, the birdcatcher sets out in the early spring morning, carrying his decoy in his cage in a handkerchief. When the country is reached, and the decoy, all in the dark, hears the voices of its free fellows among the boughs, it breaks out, and returns them note for note as long as they please to keep the game up. By-and-by the birdcatcher marks a tree whence issue chaffineh notes the boldest and most defiant. It is said by these men (and it is their business to know) that never more han a single pair of chaffinehes live in a tree. the foot of the tree containing the hold free bird, the birdeatcher places his decoy, covering it over-cage, handkerchiof, and all—with a handful of grass. Then he sticks the little branch on which the stuffed bird is mounted into the trunk of the tree, and just

## Chailletiacee

limed whalebone twigs. Then the man retires. Mean-while the free bird in the tree, with its hen near at hand, has heard the voice of the decoy, and, trembling water, has neared the voice of the decay, and, resulting with jealous rage, has replied to, the salvos on either side becoming heavier and floreer each moment. At last the free bird, finding the mysterious stranger will not respond to the invitation to come out and fight, like a true finch, hops down in search of it. In an instant it spies the stuffed thing sitting out impudently, and, as it were, on the very steps of his castle; and, with a harsh cry, down he swoops to inflict deadly chastisement; but, has! the treacherous twigs intervene, and, halking it of its vengeance at the very moment of its consummation, hold it an ignominious prisoner till the man runs up and consigns it to the store-cage. A clever birdeatcher will thus capture from twenty to forty singing chaffinches in a single morning.

CHAILLETIACEM, shail-le-ti-ai/-se-e, in Bot., the Chailletia fam., a nat. ord. of dicotyledonous plants in the sub-class Monochlamydeæ. The only remarkable member of this family is Chailletia toxicaria, a tree growing

in Sierra Leone, producing fruit which is called ratsbane from its poisonous nature.

Chain, tshaine (Fr. chaine, Lat. catena), a series of links or rings connected or fitted into one another, usually made of some kind of metal; as a chain of gold or of iron; but the word is not restricted to any particular kind of material. It is often used for an ornament about the person.

CHAIN CUILE. (See CABLE.)
CHAIN MAIL, or ABMOUR, a flexible kind of armour made of hammered iron links connected together. was much worn in the 12th and 13th centuries, and was lighter and more convenient than armour composed of steel or brass plates. It was not, however, so complete a defence against the thrust of a lance or spear.

CHAIN RULE. (See EQUATIONS.)
CHAINS, in Mar., strong links or plates of iron, the lower ends of which are bolted through the ship's sides to the timbers. They are used in order to contain the blocks called "dead-eyes," by which the shrouds of the masts are extended; and are placed at short distances from each other on the outside of the ship. Top-chains are chains used in order to sling the lower yards in time of battle, to prevent them from falling when the ropes by which they are hung are shot away or injured.

CHAINS. HANGING IN, 8 species of ignominy frequently inflicted in former times upon the bodies of malefactors after execution. It consisted in hanging the body in chains upon a gibbet near the place where the crime was committed, and allowing it to rot there as a terror to other offenders. It was only in 1834 that a law was passed abolishing this practice in England. Chain, thair (Lat. cathedra, Fr. chaire, a pulpit), a movable scat or frame, made with a bottom of different mutailly such than the control of the control

a movable scat or frame, made with a bottom of different materials, and used for persons to sit in. The term was originally applied to the pulpit from which the priest addressed the people. The place where professors and regents in universities deliver their fectures is still called the chair; as the professor's chair, the chair of natural philosophy, &c. The curule chair was an ivory seat placed upon a car, in which the prime meristrates of ancient Europe and also these prime magistrates of ancient Rome sat, and also those to whom the honour of a triumph had been decreed. The sidn chair is a vehicle in which persons are carried. It is supported by two poles, and carried by two men. Though not much used at the present day, it was greatly in rogue a hundred years ago. In William Hogarth's works it is frequently represented.

Hogarth's works it is frequently represented.

CHALCEDONY. (See CALCEDONY.)

CHALDEAN PHILOSOPHY, kill-de'-an.—The ancient
Chaldees, favoured by wide plains, unclouded skies,
and clear, still nights, early turned their attention to
the study of the heavenly bodies. To them the sun,
moon, and stars were the superior intelligences who moon, and stars were the superior intelligences who created and sustain all things, and who guide the destinies of men. Hence they received divine worship and honours; and the study of their movements became a part of the priestly office. The learning of the Chaldees was greatly extolled in ancient times by Jews as well as Greeks; and they are generally allowed to have been the first people who made any considerable progress in astronomy. The determination of the lunar periods, of the equinoctial and solstitial points, a more

## Chaldron

precise definition of the solar year, the division of the coliptic into twelve squal parts, of the day into twelve hours; the signs, names, and figures of the sodisc; the invention of the dial—are among the improvements in astronomy attributed to the Chaldes. It is said that Callistenes, who accompanied Alexander the Great on his expedition, brought back with him from Babylon a series of astronomical observations extending over 1,903 years, or 2,234 years before the Christian ers. Astrology was also much practised among the priests, who, from the movements among the heavenly bodies, professed to be able to foretell future events. According to Diodorus, they distinguished the five planets by the appellation of "interpreters," because they foreshadowed the destinies of men and nations, and presided over the birth of each individual. They conpresided over the birth of each motivatual. Tasy con-ceived that besides the planets there were thirty stars, which were called the "consulting gods," twelve of which presided over the signs of the zodisc and the months of the year. Below these were twenty-four stars, of which half were to the north and visible, and half to the south and invisible, the visible being assigned to the living and the invisible to the dead; and they were denominated the "judges of the world." The interpretation of dreams, divination, incantations, and anguries, also occupied an important place in their system of knowledge.

CHALDEANS, or CHALDRES, in its widest sense and as used by the later Hebrew prophets and Greek and Roman writers, was synonymous with Babylonians, the ancient inhabitants of Babylonia; more strictly, it was applied to the people inhabiting the southwest part of that kingdom,—the country extending along the Persian gulf from the Buphrates to the Arabian desert. They are believed to have originally inhabited the Carduchian mountains, in the neighbourhood of Armenia, where Xenophon and others mention nood of Armenia, where Aenophon and others method the existence of a people of that name. At what period they descended to the plains below, history affords as no information; but at length they became so numerous and powerful as to prevail over the other inhabitants of the country, and by the time of the Jewish captivity their name had come to be applied to the inhabitants of Babylonia generally. Genenius and other recent philologists believe that the ancient name and race are preserved in the modern Kurda. The and race are preserved in the modern Kurds. Chaldmans were also an order of persons in Babylonia who are in the book of Daviel classed with the magicians and astrologers, and were consulted by the king ou matters of religion, evidently forming a sort of priest class. They also constituted the learned class of the people; and the term Chaldeans is applied by Greck and Roman writers to the whole order of the learned men of Balvylom. At a later period the name came to be given in the western parts of the world to persons who professed to interpret dreams and improvement the greatly in of others without reference. pose upon the credulity of others, without reference to

Chalder Language, käl-dee', is the name given by philologists to the castern dialect of the Aramaic, of which the Syriac is the western, and which forms the northern branch of the Semitic tongues, the Hebrew, Arabic, and some other minor dialects forming the southern branch. As the language of Babylonia at the time of the Jewish captivity, it was much used by that people after their return to their own land, and, indeed, as a written language it is now known to us only through the Jews, every trace of its literature baving disappeared, though it is still spoken by some of the tribes inhabiting the mountains of Kurdistan In the Hebrew canon, several chapters in Daniel and Bra are written in this language. As a dialect, it is distinguished from the Syriac by its avoiding diphthongs and the vowel o, for which it generally has dip the use of dagesh forts and the general accontuation of the last syllable. The mode of writing is also much less defective than in Syrisc, and in forms it is poorer than both the Hebrew and Syriac.

the place of their birth.

CHALDRON, tchal'-dron (Fr. chaudron), is an English dry measure, containing S6 coal bushels: 21 chaldrons make a score. In a chaldron of coal there are 12 sacks; and if five chaldrons be bought at one time, the vendor must deliver 63 sacks, the three additional sacks being termed the ingrain. In London and elsewhere, however the coal of the coarse of the sacks the coal of the coarse of the sacks. ever, at the present time, coals are sold by the son of

20 cwt. avoirdupois. In Newcastle, a chaldron of coals consists of 53 cwt., exactly double the London chaldron.

CRAINCE, tehalf-is (Lat. calie, a cup).—This term was formerly applied to an ordinary drinking-cup; but it is now only used to distinguish the cup employed in administering the Holy Sacrament. Silver is the metal of which chalices are usually made; but they are often of gold or gilt, and studied with jewels. They are sometimes made of agate, crystal, or glass; but, on account of their fragile nature, these substances are

account of their fragile nature, these substances are seldom employed in their manufacture.

CHALE, tshauk (Lat. calx, lime), a variety of limestone; or carbonate of lime, of a soft, earthy nature, generally of a yellowish-white colour, and sometimes pure white. It often forms strats of great size. It has an earthy fracture, is easily broken, and is rough to the touch. Some varieties of chalk are so compact that they can be employed as building-stones when cut or sawn into shape. After being burnt into quicklime, chalk is converted into mortar, in which shape it is much used. Silies, alumins, and magnesis are often present in chalk, and when these are removed by pounding and diffusing in water, it becomes whiting. Chalk is also largely used in the manufacture of soda, ADBLE IS RESO LETGELY USED IN the manufacture of soda, for the purpose of decomposing the sulphate of soda in the "balling" process; and it is also used as a manure. (See LIME.) Perfectly purified chalk, when mixed with vegetable colouring matters, such as turmeric, litmus, and saffron, forms pastil colours. Vienna white is merely purified chalk. (See CEANON.)

CHALLENGE. (See JUNY.) CHALLENGE TO FIGHT, tshill-lenj (Norm, chal-lenger, to claim), is an offence tending to provoke or misdemeanour to challenge to fight, either by word or letter, or to be the bearer of such challenge, and punishable by fine and imprisonment, according to the circumstances of the case; and a person who sends such challenge is liable to be apprehended and bound over in a recognizance to be of good behaviour.

CHALYBEATE SPRINGS, kāl-ib'-e-aif, natural waters containing iron in solution. For a full account and analysis of the most famous chalybeate springs, see MINERAL WATERS.

CHAMBLAUCIACRE, kam-e-law-se-at-se-e, in Bot., the Fringe-myrtle fam., a nat. ord. of dicotyledonous plants in the sub-class Calyciflorae. This is a small group of shrubby plants only found in Australia, having evergreen dotted leaves. They are nearly allied to Myrtacae, but may be distinguished from them by their heath-like aspect, their more or less pappose calyx, and by their truly eigenple leadled over and by their truly simple 1-celled ovary.

and by their truly simple I-celled ovary.

CRAMEROPS, kim'e-rops, in Bot., a gen. of Palms.

C. Agmilis is the only palm found wild in Europe.

Fibres obtained from it have been used as a substitute for horse-hair, and in Sicily the different parts of this plant are employed for making walking-cames, hats, baskets, and other useful articles. The materials from which the Brazilian chip or grass hats are manufactured are obtained from the species C. orgentea.

GRANDER, tehaim'-ler (Lat. camera), a portion of a house or of an apartment. The term is ordinarily a noise or or an appearance applied to a room intended for sleeping in. In policy and mercantile matters, a chamber is the place where certain assemblies or councils are held. The term is certain assemblies or councils are held. certain assembnes or councils are held. The term is also applied to the assemblies themselves, whether established for state purposes, for local government, for the administration of justice, or for the direction of commercial affairs. A chamber of commerce is a body of merchants and traders, who associate together in order to promote the mercantile interest of the town or district to which the society belongs. Chambers of commerce were first introduced into Scotland from the

commerce were first introduced into Scotland from the continent at the close of the last century.
Cinagens, in Mil., a term applied to a part of the hore at the breech end of a piece of artillery or smallerm. It contains the powder, but is contracted, so as not to admit the shot or shell. Chambers are of different forms, some being spherical, some cylindrical, and others conical or pear-shaped. The loading and firing of chambered guns are slower than those without chambers. They are generally used when the weight of the thot or shell is great in comparison with the charge that the shot or shell. Chambers are of different forms, some being spherical, some cylindrical, dothess conical or pear-shaped. The loading and ing of chambered guns are slower than those without amplers. They are generally used when the weight of the arms are slower than those without amplers. They are generally used when the weight of the animal at once contradicts both statements. Indolent and sluggish as it may appear, it

of powder. The chamber of a mine is the place, mostly of a cubical form, where the powder is confined.

CHAMPELIAIN, I than "berlein (Fr. chambellen;
Lat. cubicularius, prafectus cubiculi), is variously used

in our laws, statutes, and chronicles.

in our laws, statutes, and chronicles.

CHARREALIN, THE LORD GEREA, is an hereditary officer of great antiquity, and was once of the highest dignity in the state. The office was conferred by Henry I. on the family of De Vere, earls of Oxford, and was enjoyed by them for nearly six hundred years. On the death of the eighteenth earl, without issue, the honour descended, by a female heir, to the family of Bertie, and is now held jointly by the families of Chemondeley and Willoughby d Bresby, each family estigoring it alternately in each succeeding reign. He attends on the king at his coronation, has the care of the palace at Westminster, the fitting up of Westminster Hall for coronations, feasts, and other great occasions; he attends upon peers at their creation. occasions; he attends upon peers at their creation, and upon bishops when performing their homage to the sovereign. Many perquisites and fees belong to the sovereign. Many perquisites and fees belong to this office; but the former are usually compounded for at the performance of any of those ceremonies where they are claimed. The delivery of the sword of state to a distinguished member of the existing administration is left wholly to the choice and discretion of this official. Upon all occasions of public ceremony, the keys of Westminster Hall and of the Court of Requests are delivered to him, and at these times the gentleman usher of the black rod, the yeoman usher, and the doorkeepers, are at his command.

CHAMBERLAIN, LORD, OF THE HOUSEHOLD, who is not to be confounded with the preceding, is an officer of the royal household, having superintendence and control over all the servants employed about the royal chambers, except those of the bedchamber. The royal chaplains and other officers of the chapel royal, the physicians, surgeons, and apothecaries of the house-hold, as well as the royal tradesmen, are by his appointment. He has the oversight of the queen's band, and of all comedians, trumpeters, and messengers. The performance of stage plays in the metropolis and at Windsor, and wherever there is a royal palace, is not legal unless in a house or a place licensed by the lord chamberlain, whose license is also necessary to render legal the performance of a new play in any part of Britain. Persons to be presented at levees or drawing-rooms are required previously to scud their cards to him, and it is his duty to see that such persons are entitled to be presented to the sovereign. He is always a member of the privy council, and his tenure of office expires with his party. He has a salary of £2,000 a year, and is assisted in his duties by a vice chamberlain, whose tenure is also dependent on the administration, and who has a salary of £924.

CHAMBERTAIN OF THE CITY OF LONDON is an officer of considerable trest and dignity. He acts as treasurer of the corporation, regulates the admission of freemen, and settles all disputes between masters and apprentices. He is chosen annually by the livery at large; but in practice the office is usually for life, the same person being re-elected each year. Chamber Ardente, shumbr-ar-dant (Fr., burning

chamber), in French Hist., was the name given to a tribunal, established by Francis I. about 1535, for the special object of trying and condemning heretics to be burnt. Afterwards the name was given to the extra-ordinary commissions established under Louis XIV. for the examination of prisoners, and, under the re-gency of the duke of Orleans, against certain officers of the public revenue.

CHAMBRE INTROUVABLE (Fr., the undiscoverable chamber), in French Hist., was a name bestowed, in ridicule, on the chamber of deputies which met after the second restoration of Louis XVIII. (1915), on ac-

count of its coldness and anti-nationality.

CHAMELEON, kim-e'-le-on.—This reptile has probably been the subject of more delusion than any other member of the animal kingdom. The two most

489

## Chameleon Mineral

has an appetite for comething more substantial than air, and enjoys an exercise of its limbs as much as any other reptile. The most curious part of the air, and enjoys an ereroise of its lambs as much as any other reptile. The most curious part of the animal is its tongue; and it is owing to the singular nature of this organ that the erroneous idea arose of its subsisting on air. This tongue is composed of a nollow tube, which is terminated by a fleshy knob, and has a oup-like cavity in its anterior surface: this is covered with a glutinous secretion. By a wonderful provision the animal can dart its tongue with lightning-like swiftness and extraordinary sureness of aim at its press. The guickness of this proceeding, together with prey. The quickness of this proceeding, together with the length of time the chameleon will exist without food, may, in a great measure, account for the popular delusion. With regard to its colour-changing propensity much might be said and quoted; only that it is not needful, as this phenomenon has been frequently and satis-factorily explained. The result of Mr. Milne Edwards's investigation is, in substance, as follows:—Beneath the transparent epidermis of this reptile there is a great quantity of minute soft granules, which bear the dif-ferent colours: these are more or less extended, according to the quantity of blood that reaches them, and the change of colour is thus effected. The changes it really will undergo under certain powerful excitements are from its natural colour, pale grey, through pale green to yellow and dingy red, and sometimes, but rarely, nearly to black. The chameleon is a most sluggish animal, and will sit for hours on the branch of a tree, scarcely giving any token of its existence be-youd an occasional roll of its singular eye, which possesses the property of independent motion; and thus, while one eye is quite motionless, the other will pro-trude from the animal's head, and glare in a hideons fashion. Then, perhaps, suddenly it will dart out its tongue oftentimes to twice the length of the whole animal, and whick some unfortunate insect into its jaws. The period of time a chameleon will exist without food is astonishing. Hesselquist makes mention of one he kept for a month, which during the whole time, as far as he could ascertain, did not eat a single insect. Of this genus there are about eighteen species, all of which are natives of the Old World, principally to be found in Africa and Asia. Some species, however, have been naturalized in Europe.

CHAMELEON MINERAL.—Manganate of potash was so called from the changes of colour apparent in an alkaline solution of the salt. It is made by fusing binoxide of manganese with carbonate of potash in an open

CHANOIS, sham'-moi (Antilope rupicarpa). — The chamois is rather larger than the roebuck, and, when full grown, weighs from sixty to eighty pounds. colour changes with the seasons. In summer it is of a dusky yellowish brown, and in winter jet black, excepting the hair of the forehead, the belly, and the tufts of hair that overhang the hoofs, which is tawny, and remains so always. The black stripe, too, extending from the eyes to the mouth is permanent. It has been a disputed point whether the chamois should be classed with the goat or the antelope genus. Examina-tion, however, shows that there is really but little affinity either in the structure of the animals or their habits. The frontal bone of the chamois just before the horns is concave; that of the goat is convex. The horns of is concave; that of the goat is convex. The horns of the latter recede; those of the former advance, and are perfectly plain and smooth, while the goat's horns are wrinkled. More than all, the chamois is well known to avoid spots favoured by goats; and no instance has ever been shown where a female of either species has brought forth a cross-bred kid. The head of the chamois exhibits in its construction a wonderful blending of lightness and strength. The frontal bones are so of lightness and strength. The frontal bones are so fragile that a rap of a man's knuckles would suffice to shatter them, that is, if they were unsupported; but they are supported, and in a marvellous way. Over the first set of bones a second is thrown, and between the walls are arched cells and substantial girders of solid

#### Chamois

point it is dense and solid. The hollow part fits over a bony protuberance growing out of the skill itself. The horns of a full-grown buck measure about neven inches in length, the points being extremely sharp, and hooked backwards. At first sight it would seen that see weapons of attack or defence, the chamois horse, from their formation, would be next to useless. This however, is far from the state of the case. When fighting the aborton larger his however have the contractions of the case. ing, the chamois lowers his horns under the thron ing, the chamois lowers his horns under the throat we his antagonist, or turns his head sideways, that the sharp point may come against the shoulder of the enemy, and then, drawing them back vigorously, inflicts a most formidable gash. The horns of the male chamois are thicker and altogether stronger-looking than those of the female; they do not diverge from each other

CHAMOIS.

in so straight a line as do hers, but describe a slight curve as they rise upwards and apart from each other. The horns of the doe are not so abruptly hooked as those of her mate. Except when running, the gait of the chamois is extremely awkward. The cause is evident. In the first place, its hoofs, shaped like those of the sheep, but longer and more pointed, are calculated for sliding rather than for stepping, and, in the second, its hinder ranner than for stepping, and, in the second, its hinder legs have every appearance of being longer than the fore. A hunter afoot would probably overtake a cha-mois fleeing over a level plain; but among its native ice-bills the case is very different. Then the true pur-pose of the awkward-looking hind legs appears. Not only do they serve as springs, enabling him to perform princulous fiving leave from case to great but the miraculous fiving leaps from crag to crag, but they break the concussion that would otherwise certainly break the concussion that would otherwise certainly occur in a leap from a great height, and enable the animal to alight with safety and freedom. A perpendicular wall of rock smooth as glass, and twelve or fifteen feet in height, is no impediment to the upward flight of a chamois. He will leap against the slippery wall, and, striking it with his hind feet, obtain a renewed apring, rebound again in an opposite direction to some higher bank, and there find firm footing on a patch so small that a man's two hands could cover it. The food of the chamois consists of such herbs and lichens as grow on the mountains; when, however, the winter sets in so flereely that every green thing perishes, the animals shift their quarters from the steeps to the woods that grow at their bases, and there subsist on grass and leaves. An odorous dark-coloured ball is found in the stomach of the chamois, and probably owes its formation to the fibrous and resinous nature of the substances on which it feeds. At the pairing season, a sort of bladder beneath the skin of the buck's borns develops itself. This bladder contains a lymph of a strong musk-like smell, and, if shot at this season, the skin of the head will retain the scent for many years. At this scented period the chamois bucks, incited years. At this scented period the chamois buoks, nontear by jealousy, have most tremendous combats together, and it is at this season that the hunter can easily decay them to within gunshot by imitating their love-call. The young are born in May, the chamois doe having sometimes two kids at a birth, but frequently but one, the pairing season is November; the period of gestation about twenty weeks. It is only about November that the full grown partiarched luncks roam at large, walls are arched cells and substantial girders of solid bone. The arched girders which occupy the space between the upper and lower surface rise, bridge-like, with a spiral twiet, and here and there a flying buttrees will give additional strength to the walls, or a lateral track help to support the vault above. The horns of the chamois are very curiously constructed. Up to a the chamois are very curiously constructed. Up to a sertain point the horn is hollow, and thence to the most secluded and inaccessible places. No animal approach that the full-grown partiarchal bucks room at large, the remaining portion of the year keeping close in the most secluded and inaccessible places. No animal approach the support of the serial point the horn is hollow, and thence to the

#### Chamomile

ossesses so tough a skin as the chamols. It will some possesses so tough a same as any bullet will send one times happen that the hunter's bullet will send one toppling over a precipice nearly a thousand feet deep; but though every bone in its body be smashed by the Tall, the hide will remain intact.

CHAMOMILE. (See ARTHBHIS.) CHAMP DE MARS and CHAMP DE MAI, shawn(g)-dewar (Fr.), in early French Hist., denoted certain public assemblies of the Franks, which were instituted as early as their conquest of Gaul in the 5th century. At first, these were held annually in the month of Masch, and were hence called the March-fields (Champ de Mars); but in the 8th century king Pepin transferred the time of meeting to the month of May; whence they were termed May, fields. At these meetings, the king, courtiers, bishops, nobles, and people, assembled together for the discussion of public affairs, such as war, peace, the enactment of laws, all which questions were decided by the majority. The common people, however, long neglected their privilege of attending, and were at length deprived of it. Charleattending, and were at length deprived of it. Charle-magne in some measure restored it to them by order-ing that every count should bring with him thirteen assessors, or the same number of the most respectable men within his jurisduction, to represent the people in the general assembly. The first descendants of Capet departed from this usage; but Philip IV. (1285-1314) restored the third estate by calling together delegates

from the cities.

CHAMPAGNE WINE, sham'-pain, is produced from the grapes grown in Champagne, an aucient province of France. This favourite wine is divided into two classes,—white and red champagne. The former is made either sparkling or still. Sparkling champagne (mousseux) is produced by treating the wine in a particular manner during fermentation. The wine racked off in December, and after being fined with isinglass, is bottled and securely corked. Carbonic acid is generated in the wine on account of the incomplete nature of the fermentation, and its effer-vescing qualities depend upon the quantity of that gas dissolved by the fluid. After the sediment which is deposited has been removed, a liquor, composed of a solution of sugar-candy in Cognac, is added, and each bottle is tightly re-corked. Still Champagne is first racked off in the March after the vintage. The white Champagnes of Rheims and Sillery are considered the Those of Sillery are pale amber-coloured, dry spirituous, and possess a superior bouquet; those of Ay and Mareuil are more sparkling and less spirituous. There are several varieties of first-class red champagnes. On account of the profitable nature of the pagas. On account of the promator nature of the manufacture, and the popularity of Champagne wine, it is much adulterated with the juice of pears, goose-berries, &c. Very little of the wine sold as Champagne in Paris is really genuine. It generally consists of some cheap light white wine charged with carbonic soid gas.

CHAMPEUTY, cham!-per-te (Lat. campi partitio Fr. champart), in Law, is a species of maintenance, and punished in the same manner, being a bargain made by a man with a plaintiff or defendant campum partire,—to divide the land or other matter sued for between them, if they prevail at law; whereupon the champertor is to carry on the party's suit at his own expense. Thus champart, in the French law, signifies a similar division of profits, being a part of the crop annually due to the landlord by bargain or custom. In our sense of the word, it signifies the purchasing of a suit, or the right of suing,—a practice so much abhorred by our law, that it is one main reason why a chose en action, or thing of which one has the right, but not the possesis not assignable at common law, because no man sion, is not assignable at common law, because no man should purchase any pretence to see in another's right. By the Roman law, such offenders were punished by the forfeiture of a third part of their goods and by perpetual infamy. Hitherro must also be referred the provision of the statute 32 Hen. VIII. c. 9, that no one that are the provision of the statute 32 Hen. VIII. c. 9, that no one shall sell or purchase any pretended right or title to land, unless the vendor bath received the profits thereof for one whole year before such grant, or hath been in the actual possession of the land, or of the reversion or remainder, on pain that both purchaser and vendor shall each torfeit the value of such land to the king

## Chancellor, Lord

CHAMPIGNON. (See AGARIOUS.)

CHAMPIGNON. (See AGARIOUS.)

CHAMPION, tehdw-pre-on (Fr.), in the Middle Ages was a pers on who took up the cause and fought in the room of another, who from age, infirmity, or other cause, might, be so represented. Single combst was one of the ways frequently adopted in the Middle Ages to decide the right of a cause; and women, children, or aged persons, were allowed to appear by a representative. At one time the champions formed a particular class, were compelled to wear a particular dress, and were looked upon as disreputable, being ready for hire to take up any quarrel. At a later period, however, during the ages of chivalry, the champion was a knight who entered the lists on behalf of an injured lady, achild, or one incapable of self-defence. The king's child, or one incapable of self-defence. The king's champion of England is a very sucient office, and is annexed to the Scrivelsby estate in Lincolnshire, having been held by the Dymoke family for many generations. The champion, armed cap.a.pic, and mounted on horse-back, enters Westminster Hall during the coronation banquet, and proclaims by a herald "that if any one shall deny the king's title to the crown, he is there ready to defend it in single combat; after which the king drinks to him, and then sends the cup to the cham-pion, who drinks, and then carries off the cup as his

CHANCE, tshance, may be said to denote the cause or mode of happening of an event which is unexpected, or the cause of which is not manifest to human reason. Originally, it was applied to events which were believed to happen independent of any law or cause; but this is a sense in which it is now seldom or never employed; for both reason and revelation assure us that there is no such thing as chance in this seuse. Everything has its own law and its proper cause, and chance merely denotes that we do not know the proper cause nor the

democrating to which a phenomenon occurs.

CHANCEL, tshôn'-sel (Lat. cancellus, a acreen), the name given to that part of the choir of a church between the communion-table or altar and the balustrade or rail that incloses the space where the ultar is situated. The term is generally confined to parish churches which have no aisles round the choir, or chapels con-nected with it. Sometimes the chancel and the choir are synonymous. Before the Reformation, the service was always performed in the chancel, and at that time the clergy were held to have a special right to it. the present day, its repairs generally fail upon the impropriator or rector, and not on the parish. The impropriator or rector has a right to the principal pew in the chancel, but he cannot erect a tablet there withont the leave of the ordinary. The chancel corresponds with the bema of the ancient basilica.

CHANCELLOR, tshan'-sel-lar (Lat. cancellarius, from canadh, nattice-work or railings), denoted originally a porter or doorkeeper,—one stationed at the lattice-work of a window or doorway to introduce visitors. Afterwards, under the later emperors, the name was given to a kind of secretary or scribe in the courts of law, from his position behind a screen or lattice-work separating him from the rest of the hall of Gradually he appears to have risen in power and authority, and to have acquired certain judicial powers and a kind of superintendence over the other officers of the empire. From the empire the title and office passed to the Roman church, and hence every bishop still has his chancellor, the principal judge of his consistory: and when the modern kingdoms of Europe were established upon the ruins of the empire, almost every state preserved its chancellor, with different jurisdictions and dignities, according to their different constitutions. In all he seems to have had the supervision of all charters, letters, and such other public instruments of the crown as were authenticated in the

most solem numner; and therefore, when seals came to be used, he had the custody of the king's great sail. CHANCILLOR, LORD, in England, was originally the sovereign's chief secretary, and, from the nature of this office, his adviser, and was hence called the keeper of the king's conscience. Pattions and alarms are of the king's conserience. Petitions and claims were referred to him, and he formully prepared the royal grants and charters, affixing the king's seal to them. He thus became keeper of the great seal, and was shall each forfeit the value of such land to the king invested with great discretionary power. He is created and the prosecutor. (See Barrater, Maintenance.) by the will of the sovereign, by the mere act of deliver-

492

## Chancellor of a Bishop

Chan-Books

ing the great seal into his custody, and he holds office during the pleasure of the crown; but practically he resigns office with his party. He is, by prescription, speaker of the House of Liords, and, by wirtue of his office, a member of the privy council. He issues writs for summoning parliament, and transacts all business connected with the custody of the great seal. He is principal advisor of the crown in matters of law, chiefjudge in the Court of Chancery, and the head of the profession of the law. He appoints nearly all the judges of the superior courts, the commissioners in bankruptcy, and the judges of the county courts; appoints all justices of the peace, though usually upon the recommendation of the lords-licutenant of the several counters, and is patron of all crown livings rated under menation of the lords-leutenant of the several counties, and is patron of all crown livings rated under \$20 (in the reign of Henry VIII.). He is visitor, in right of the crown, of all hospitals and colleges of royal foundation; has the general guardianship of all infants, idious, and lunatics; and exercises a special jurisdiction to the contraction of t natures, and trunstics; and exercises a special jurisdiction in questions relating to charities and trust estates. He ranks above all dukes not of the blood royal, and next to the archbishop of Canterbury. He has a salary of £10,000 a year, and an annuity of £5,000 on retiring from office. There is also a lord chancellor in Ireland, whose authority within his own jurisdiction is in most cases the same as that of the lord chancellor of Great Britain. He is appointed only during pleasure, and retires with the political party at whose instance he had been appointed. His salary is £8,000 per annum. In Scotland, prior to the union of the two kingdoms in 1707, there was also a lord chancellor, whose duties were analogous to those of the lord chancellor of Great Britain. At the Union this office was abolished, and in its place that of keeper of the great seal was created, for affixing the great seal to such writs as have to pass under it.

CHANCELLOR OF A BISHOP OF DIOCESE, is vicargeneral to the bishop, directing and assisting him in all matters of ecclesiastical law, and holding his courts for him. It is not necessary that he be an ecclesiastic, but, if a layman or married, he must, by the canons, be

Dut, it a layman or married, he must, by the canons, be at least a master of arts or a bachelor of law.

CHANCELOR OF A CATHIDRAL, is an officer who superintends the arrangements for the regular performance of the religious services.

CHANCELOR OF A UNIVERSITY, is usually the highest officer of the university, and exercises exclusive jurisdiction in all questions that concern the

members of the university.

Chancellog of the Duchy of Lancaster, is an officer appointed chiefly to determine controversies between the king and his tenants of the duchy of Lancaster. The court is held at Westminster, but is not much resorted to, and is usually presided over by the chancellor's deputy.

CHANCELLOR OF THE EXCHEQUER. (See EXCHE

CHANCELLOR OF THE ORDER OF THE GARTER, and other orders of knighthood, is an officer who seals the commissions and mandates of the chapter and assembly of the knights, keeps the register of their proceedings, and delivers acts thereof under the seal of their order. He also exercises various functions at the installation of the knights.

CHANCE-MEDLEY, OF CHAUD-MEDLEY.—The former signifies a casual affray, the latter an affray in the heat of blood or passion, in which death ensues to the assailant. The law authorizes a man to protect himself from an assault or the like, in the case of a sudden brawl or quarrel, by killing him who assaults him, and considers it justifiedth homicide. It does not apply to a case of attacking, and only when certain and immediate auffering would be the consequence of waiting for the assistance of the law. Wherefore, to excuse homicide by the plea of self-defence, it must appear that the slayer had no other possible, or at least probable, means of escaping from his assailant. If he had, then the offence would amount to mantaughter, or, possibly, sawder, according to the circumstances of the case, and the distinction made by the law in determining whether the one or the other crime had been committed. from an assault or the like, in the case of a sudden whether the one or the other crime had been committed Any accidental or unpremeditated killing of a person. without negligence or carelessness, us by a werkman throwing down rubbish from a house after giving suffi-dient warning, or an officer whipping a criminal in a 488

reasonable manner, and such like, is chance-medley and misadventure.

misadventure.

Changery. (See Court of Changery.)

Changery. (See Court of Changery.)

Changer States, shin-dos', is applied to a distinct of the Reform Bill which gives the franchise to temantic under lease or at will in the counties paying not best than £50 of rent. A motion to this effect was made by the marquis of Chandos, and carried, after much opposition, by a majority of eighty-four. (See Resour.)

Bill.)

CHANGELING, tahainje'-ling (Ang. Sax.).—It was at one time a common superstition that young children were liable to be stolen or changed by fairles before being baptized; and hence they were carefully watched being Daphtzeu; and nence they were carefully wascusare till that ceremony was over. It was thought that the fairies were always anxious to change their own starve-ling elves for the more robust children of men. The children so left were called changelings, and were known by their greater backwardness in growth or learning: hence stunted or idiotical children were re-

garded as changelings.

CHANNEL, tshan'-nel (Fr. canal), a passage or place of flowing. The term is generally applied to a water-course. The deeper part of a river, through which the principal current flows, is generally called the channel. The strait or narrow sea between two islands, or a conti-

The strait or narrow sea between two islands, or a continent and an island, is also called a channel; as the British Channel, the Irish Channel, &c.

CHANT, tshant (Fr. chanter, to sing), in its most extended sense, is applied to the musical performance of all those parts of the liturgy which by the rubric are permitted to be sung. More particularly, and as distinguished from singing, it is applied to that plain tune to which the prayers, litany, &c., are set in choirs and places where they sing. In the chant, when properly and fully performed, both the minister and the choir bear their respective parts, the minister reciting the prayers and all the parts of the service which he is enjoined to say alone (except the lessons) in one sustained note, occasionally varied at the close of a cadence, and the choir making the responses in harmony, sometimes in unison. In the Psalms and Cautimony, sometimes in unison. In the Psalms and Canti-cles both the minister and choir join together in the chant without distinction, each verse being sung in full harmony. The chanting of prayers has always been observed in the principal of our cathedrals. In church history we meet with different kinds of chants er songs; as the Ambrosian, introduced by St. Ambrose; the Gregorian, by Pope Gregory the Great .- Ref. Hook's

Church Dictionary.

CHANTEN, tshim'-tre (Lat. cantaria), was a little chapel or particular altar in a cathedral church, built and endowed for the maintenance of a priest to say or sing masses for the soul of the founder, and such others as he might appoint. There were many of these in England before the Reformation; but in the thirty-seventh year of Henry VIII. the chantries were given to the king, who had power at any time to issue commissions to seize their endowments, and take them into his possession; and such as were not then seized

were afterwards vested in his successor, Edward VI. Chaos, kai'os (Gr.), is applied to the confused mass or the state of confusion, in which matter is supposed to have existed before it was reduced to order by the creating power of Deity. In the ancient Greek mythology, chaos was the vacant infinite space which existed before the creation of the world, and out of which sprang all things that exist. Chaos, secording to Hesiod, produced by and out of itself Erebus and Night, who in turn were the parents of Æther and

CHAP-BOOKS, tshap'-books, is the name given to a kind Char-Books, thidp'-books, is the name given to a sinal of literature that was at one time very common in this country. The designation is probably derived from their forming part of the stock in trade of the chapman or travelling merchant. They were of inferior paper and typography, and the older of them, in the early part of the seventeenth century, are printed in black letter, in the form of small volumes. Their contexts were of a very wiscellenger nature, conversions tents were of a very miscellaneous nature, comprising lives of heroes, martyrs, and other remarkable persons; stories of ghosts, giants, witches; dream-books, &c.
The Penny Chap-books, were a later and an inferior
class of literature. They consisted usually of a single
sheet of paper, folded so as to form twenty-four pages.

p 9

Charcoal

Their contents were chiefly narratives either in prose or verse, and were characterized by a considerable degree of broad humour, and frequently not without a goodly sprinkling of obsenity. This class of literature was at one time very popular, and has scarcely yet passed out of use in the more remote parts of England and Scotland. It is said that nearly all these Penny and Scotland. It is said that nearly all these Penny Chap-books were the production of one man, Dougald Graham, who, previous to his death in 1789, was bell-man or town-erier of Glasgow.—For further information on this subject, see Chambers's Encyclopædia and the authorities therein referred to.

Culrus, tshap'-el (Lat. capella, Fr. chapelle), is an edifice for public worship, usually of a lower order, or not possessed of the same privileges, as a church. or not possessed of the same privileges, as a church. Whore parishes are large or populous, parcehial chapels, or chapels of ease, have frequently been erected for the accommodation of the people, with the consent of the bishop; and many of these have had districts assigned to them with the cure of souls, and the right of celebrating bapbisms, marriages, &c., under special acts of parliament. Dissenting places of worship are also usually called chapels. The term is also applied to places for the celebration of religious worship in the houses of noblemen, hospitals, colleges, and similar establishments. In Catholic countries the term chapel is used to designate separate erections either within or attached to a church or cathedral, and devoted to special services. These are also called chantries. (See CHANTEY.)

CHAPEL, in a printing-office, is an association of the CHAFEL, in a printing-onice, is an association of the workmen for the purpose of enforcing order and regularity in the office, and settling any disputes that may arise. It takes cognizance of all offences, real or imaginary, committed within the office, and punishes by the infliction of fines. The president is elected by the other workmen, and is termed the "father of the

CHAPERON, shap'-e-ron (Fr.), a hood or cap worn by the knights of the Garter. It was formerly worn by men and women of every degree, and ofterwards ap propriated by the doctors and licentiates in colleges, &c. The name afterwards passed to certain little shields and other funeral devices placed on the heads shields and other funeral devices placed on the heads of horses at pompous funerals. A person who acts as a guide or protection to a lady at a public place is called a chaperon, probably because the cap or hood was formerly worn by persons acting in a like capacity. Chapters, thurb-c-ters (Fr. chapters), signified, in our ancient common law, a summary of such matters as were to be inquired of or presented before justices in evre, instices of assize or of the peace in their

in eyre, justices of assize or of the peace, in their sessions. These chapiters are now those articles which

are delivered by the justice to the inquest or jury.

CHAPLAIN, tshäp'-lain (Lat. capellanus), is properly
a person who performs divine worship in a chapel, as a person who performs divine worship in a chapel, as distinguished from one who officiates in a parish church. Hence it is also applied to those who are engaged to perform religious services in the army and navy, in families of distinction, hospitals, workhouses, &c. The mobility enjoy the right of appointing a certain number of private chaplains who are entitled to certain privileges respecting the holding of benefices, &c.; thus, an archbishop may have eight, a bishop or duke six, a marquis or earl five, a viscount four, &c. Chapter, takip-let (Ital. ciapelletto), is a string of beads made use of by Roman Catholics and others to count the number of their prayers. Its invention is by some attributed to Peter the Hermit, by others to St. Dominick, who is said to have received one out of heaven from the Virgin Mary. (See ROSANX.)

believed to support Nestorianism. They were—1. the writings of Theodore of Mopsuestia; 2. the books which Theodoret of Cyrus wrote against Cyril's anathemas of the Nestorians; and 3. the letter which ihas of Edessa published against the council of Ephesus which condemned Nestorius. They were condemned by the emperor Justinian in 544; but the African and Western bishops, especially Vigilius of Rome, opposed the edict.

CHARACER, kä-rai'-se-e, in Bot., the Chara fam., a nat. ord. of acotyledonous plants, in the sub-class Acrogenæ, water-plants with distinct stems branching in a whorled manner, sometimes transparent and some

in a whorled manner, sometimes transparent and sometimes coated with carbonate of lime. They coour in stagnant, fresh, or salt water in all parts of the globe, but most abundantly in temperate climates. When in a state of decay, they give off a very footid odour, which is considered to be very injurious to animal life.

CRARACTER, kdy'-āk-ter (Lat. character, Fr. cornetère), in Bet, the term usually applied to a list of the points by which any particular variety, species, genus, sub-order, order, sub-class, or class, is distinguished from another. There are two kinds of characters, called respectively essential and natural. By an essential character is understood an enumeration of those points only by which any division of plants may be distinguished from others of the same nature. A natural character, on the other hand, is a complete natural character, on the other hand, is a complete description of a given species, genus, order, or class, including an account of every organ, from the root upwards, through the stem, leaves, flowers, fruit, and

CHARADE, sha-rade' (Fr.), is a kind of riddle, in which a word of several syllables is taken, and an enigmatical description of each of its syllables given enigmatical description of each of its syllables given separately, and then a similar description of the whole word. The descriptions should be so contrived as to be in some way connected together. The following is a good example, from the French:—"My first makes use of my second to eat my whole:" the first being chien, a dog; the second dent, a tooth; and the whole chiendent, dogs grass.

Charronroux. shar-hon-roo! (Fr.) charcos are

Charbonhoux, shar-bon-roo' (Fr.), charcoal pre-pared below a red heat, by which means it retains a considerable portion of oxygen and hydrogen. Ordiconsiderable better to organize and any charcoal contains 90 per cent. of carbon; while charbonroux contains only 70 per cent., the remainder being oxygen and hydrogen. Gunpowder made with this charcoal appears to inflame with greater energy than that made with ordinary charcoal. On theoretical grounds, however, it appears to be inferior to ordinary

powder.

Chargoal, tshar'-kole.—This well-known substance exists under a great number of forms; such as gasarbon, coke, wood-charcoal, lamp-black, and ivery-black. Gas-carbon is a very pure kind of charcoal gradually deposited in the insides of gas-retorts. Coke is dense charcoal, made by burning coal in a retort or coke-oven from which the air is excluded. It is much used as a fuel for locomotives, from giving out no smoke, and from being much lighter than coal. Wood-charcoal, although but little used in England as a fuel, is a very important element in the mannfacture of gunpowder. The most perfect charcoal is, of course, that which is used in this manufacture. (See Gun-rowders.) Thoroughly-burnt charcoal is bluish black, and varies in density according to the porosity of the wood from which it was made. Charcoal possesses the CHARCOAL, tshar'-kole.-This well-known substance wood from which twas made. Unarcoal possesses the wonderful property of absorbing gases. (See Careon.) Lamp-black is carbon deposited by any combustible burnt without sufficient sir. (See Limbert Lory-black, bone-black, or animal charcoal, will be found described under the head of Ivory-black. St. Dominick, who is said to have received one out of heaven from the Virgin Mary. (See Rosary.)

Chapman, tahip-min (Old Eng. cheap, a market), denotes generally a merchant; but it is commonly ministed to one who deals only in small articles,—one who traves the country and attends markets.

Chaptar, tahip-ter (Lat. capitulus, from asput, the head) is applied to the society of canons in a cathedral or collegiate church, of which the dean is the head, and which form the council of the bishop. (See Canon.)

Attached to many cathedrals and collegiate churches are buildings for the meeting of the chapter, called sare buildings for the meeting of the chapter, called sare buildings for the meeting of the chapter, called sare buildings for the meeting of the chapter, called sare buildings for the meeting of the chapter, called to many cathedrals and collegiate churches are buildings for the meeting of the chapter, called to many cathedrals and collegiate churches of chapter-houses, which are frequently alluded to in the ecclesiastical history of the 6th century, and occasioned much discussion in the Church, as they were the most perfectly non-volatile, and possessing no affinity for any other element at ordinary temperatures, it forms should much discussion in the Church, as they were

carbon ink are as legible and perfect as the first day

they were written.

CHAEG, tsharje (Low Lat. cargare, Fr. charger), is
the address delivered by a bishop or other prelate at a
visitation of the olergy under his jurisdiction. Among
Freebyterians and dissenters generally, it is a sermon
preached to a minister at his ordination, usually by
some aged or shle preacher, and bearing upon the
mature, duties, trials, and encouragements of the pastopal office. toral office.

CHARGE (Fr. charger), in Her., the name given to figures of any kind represented on a shield, which is said to be charged with whatever figures may be depicted on it. The charges on a shield should be few and simple, and as appropriate as possible to the character or achievements of the original bearer of the coat. The simplicity of armorial bearings is a strong

proof of their antiquity.

CHARGE, in Law, is an incumbrance upon property as an annuity, mortgage, judgment, or any liability to which it is made subject by a deed, will, or other instrument, or by the operation of law or equity.

CHARGE, in Mil., an expression used to denote the quantity of powder which is necessary to fire a ball, shell, or bullet from any kind of cannon or firearm. The charge for different kinds of artillery, and for dif-ferent purposes, varies from one-twelfth to one-half the weight of the projectile. Rifted cannon require a smaller charge than those with smooth bores; and in firing against a vessel or a body of troops at a short range, a smaller charge is needed for the same gun than would be required for breaching the walls of a fortress. The term is also applied to the onset made by one body of troops on another with fixed bayonets.

CHARGE D'AFFAIRES, sharf'-döf-fair' (Fr.), is the fourth, or lowest order of diplomatic agents, and is accredited not to the sovereign, but only to the individual who, for the time being, holds the office of principal secretary of state or minister for foreign affairs. Sometimes they are only empowered to act during the absence of the ambassador; at other times, they are independent of any ambassador.

CHARIOT, tshär'-e-ut (Fr.), was a kind of carriage employed in ancient times in war or for pleasure. We read of them as early as the time of Pharaoh, and they were frequently armed with scythes, as we read of them to have been with the ancient Britons. The ancient chariots had only two wheels, which revolved upon the axle, and were usually drawn by two horses. Among the Romans, however, there were also three- and four-horse chariots. The triumphal chariots of the Romans were often upon the state of the Rom

were often most splendidly adorned.

CHARISMA, kā-rie'-mā (Gr., a gift), a term frequently employed in the early Church to denote the extraordinary endowments conferred on the primitive Church; as the gift of tongues. It was also applied

sometimes to baptism.

CHARITY, thiar-e-te (Lat. caritas, from carus, dear; Gr. agape, love), one of the three great theological virtues, consisting of love to God and our neighbours, or the habit and disposition of loving God with all our heart and our neighbour as ourselves. In a narrower sense, it signifies kindness, goodwill, and forbearance towards mankind in general, and, in a still lower sense, the giving of alms. This love to our neighbours, which is one of the greatest and noblest of Christian virtues, is not of a blind, indiscriminating character. True charity attempts not to shut our eyes to the distinction between good and bad men, nor to warm our thereto between good and oad men, nor to warm our bearts equally to those who befriend and those who fajure us. It teaches us to slight and despise no man, inspiring us with forgiveness and humanity towards our enemies, with respect and esteem for good men, with candour and complacency towards our friends.

"Charity is the comforter of the afflicted, the prosector of the oppressed, the reconciler of differences, tector of the oppressed, the reconciler of differences, the intercoses for offenders. It is faithfulness in the friend, public spirit in the magistrate, equity and patience in the judge, moderation in the sovereign, and loyalty in the subject."—Barrow.

CHARITY COMMISSIONERS for England and Wales are a body of commissioners exacted by the Charitable Trusts Act of 1853, for inquiring into all charities, their nature chiagts and administration, and the action.

## Charter

to call for the production of accounts and documents from trustees, and to appoint inspectors to visit and report upon their management. Their powers do not extend to Scotland, Ireland, the universities, or London. A report of their proceedings must annually be laid before parliament.

CHARITY, SISTERS OF. (See SISTERS OF CHARITY.)
CHARITY SCHOOLS. (See SCHOOL.)
CHARITYARI, shar'-e-ve'-re, is a French term, of enectain etymology, but denoting properly a loud, discordant noise, produced by the beating of kettles, pans, and other domestic utensils, mingled with shouts, recease and bisses. In this way, provide dilibe were groans, and hisses. In this way, popular dislike was frequently manifested towards a person in France in the Middle Ages; and widows contracting second marriages, or persons of disproportionate ages marrying, were often annoyed in this way. Afterwards, the lng, were often annoyed in this way. Alterwate, the term came to be applied to political squibs and satires against public men; and in this sense it was adopted as the title of a French periodical published in Paris, corresponding to our English Punch. It may be mentioned, that the name of the German periodical of the same kind, published in Berlin, Kladderadatsch, also implies a loud, discordant noise, such as is occasioned

by the beating of kettles and pans.

CHARLATAN, sharl-a-tan (Ital. ciarlatano), denotes a mountchank, quack doctor, or empiric, and is hence applied to any one who makes loud pretensions to knowledge or skill which he does not possess. Charlatanism is to be found among all classes of society, and manifests itself in various ways, according to the object and character of the person. In literature, in science, in politics, and even in religion, there are to be found many who pretend to greater knowledge, or

be found many who precend to greater anowards, as power, or virtue, than they possess.

CHARLES'S WAIN, tsharts's wain, in Astron., the name given to seven starts in a constellation of the northern hemisphere, called Ursa Major, or the Great Bear. (See Uesa Major.) The origin of the name is not known.

CHARM, tsharm (Lat. carmen, a verse), is a magical power or spell, by which witches and sorcerers, with the assistance of the davil, were supposed to do wonderful things beyond the powers of nature. (See MAGIC.) CHARKE-HOUSE, thing-hour (Lat. caro, flesh), was a place under a church, or in a churchyard, where

the bones of the dead which were thrown up by the

gravediggers were deposited.
Charu, tsharr (Salmo salvelinus), a fish of the Salmon amily, inhabiting the lakes of Scotland, Wales, and the north of England. The body is longer and more slender than that of the trout. The back is of an olive colour, speckled with white spots, and the belly red. Its flesh

is held in high estimation.

CHART, tehart (Lat. charta), a hydrographical or sea chart for the use of navigators, exhibiting some part of the sea, or other water, with the coasts, islands, rocks, sands, bearings, &c. After the Admiralty has scanned any coast engravings, charts are engraved and sold at prices below their cost. Every available chart is supplied to men-of-war when proceeding to any particular district. At several places, such as Gibraltar and the Cape of Good Hope, depôts for charts are established. All charts are brought back to England

again, and are not re-issued without being revised.
CHARTA MAGNA. (See MAGNA CHARTA.)
CHARTA, short (Lat. charta, paper), in French Hist.,
was originally applied to the letters or charters by which the French kings conferred rights or privileges on certain towns or communities; but it is now applied to the solemn acknowledgment made by Louis XVIII., on his restoration in 1814, of the rights of the French nation. It consisted of sixty-nine articles, and in principle was somewhat analogous to the Magna Charta and Bill of Rights of the British constitution. A misconstruction of one of the articles of this charteled to the revolution of 1830. It constituted the fundamental law of the French constitution down to the revolution of 1848,

patience in the judge, moderation in the sovereign, and loyalty in the subject."—Barrow.

CHARIER, tshar'-ter (Fr. chartre), is the written care a body of commissioners expated by the Charitable are a body of commissioners expated by the Charitable their nature, objects, and administration, and the condition of the property belonging to them, with power dition of the property belonging to them, with power dition of the property belonging to them, with power ditions of private persons. Charters of the sovereign are those whereby he passes any grant to a person or body dition of the property belonging to them, with power ditions of the property belonging to them, with power ditions of the property belonging to them, with power ditions of the property belonging to them, with power ditions of the property belonging to them, with power ditions of the property belonging to them, with power ditions of the property belonging to them, with power difference of things done between man and man; and charters, are divided into those of the sovereign are those whereby he passes any grant to a person or body of the property belonging to them.

or the like. Charters of private persons instruments for the conveyance of lands. Charters of private persons are deeds and

instruments for the conveyance of lands.

CHARTERHOUSE (a corruption of Chartense, i.e. Carthusian), is an hospital, chapel, and schoolhouse in London, instituted in 1611 by Thomas Sutton, of Camps Castle, in the county of Cambridge. The site which it occupies was bought for a public burial-place during the great plague of 1349, by Sir Walter de Manny, who, in conjunction with the bishop of London, afterwards established here a Carthusian monastery. After the dissolution of the religious houses by Henry VIII., the property passed through various hands, until it was purchased for £13,000 by Thomas Sutton, who founded upon it, and richly endowed, an hospital chapel, and school, called by Fuller a "masterpiece of English Protestant and the state of the sible between the ages of ten and fourteen, and receive free board and education, there are a number who attend the school only during the day, or board with the The Charterhouse is regarded as one of the best schools in the metropolis, and many eminent per-

best schools in the metropolis, and many eminent persons have been educated here: among whom may be mentioned Dr. Isaac Barrow, Sir William Blackstone, Addison, Steele, John Wesley, Bishop Thirlwall, George Grote, W. M. Thackeray, and Sir C. Eastlake.

CHARTER-PARTY, is a mercantile instrument in writing (with or without sent), by which a party desiring to export goods from this country, or to import them from abroad, engages with some shipowner to take an entire vessel for the purpose, at a freight or reward thereby agreed for. Upon the execution of such an instrument the ship is said to be chartered or freinheld, and the narty by whom she is engaged is freighted, and the party by whom she is engaged is called the charterer or freighter. But where, instead of taking the entire vessel, the owner of goods merely bargains for their conveyance on board of her for freight (other goods being at the same time conveyed reagnt (other goods being at the same time conveyed for other proprietors), she is described not as a chartered but a general ship; and in this case no charterparty is usually executed, but a bill of lading only. It may be here stated that the word freight is sometimes synonymously used with that of eargo. (See Bill of Lading.)

CHARTISTS. tshurt'-ists, the name of a political party that sprang up in England after the passing of the Reform Bill, and were so called from their principles being embodied in a document termed the "Charter." The Reform Bill, while it conferred political power upon the middle classes, did little towards improving the condition of the working classes of society. The middle classes, too, had been assisted by the latter in their offort to obtain the franchise, and, having attained their object, they became callous or opposed to any extension of the like privileges to those beneath them in the social scale. The introduction of the new poorlaw, in 1635, was the first thing that caused any great law, in 1835, was the first thing that caused any great outery among the working classes against the purty in power, and in 1836 the "Working Men's Association" was formed in London. For some time the association did not receive much countenance; but the great commercial distress, the scarcity of work, and the dearness of provisions, that followed soon after, were severely felt by the people, and led to open and alarming demonstrations of their feelings. In the autumn of 1838 monster meetings of the working classes were convened at Birmingham and other parts of the manufacturing counties, and highly inflammatory speeches were addressed to them. The Charter was drawn up by a committee of six members of parliament and six by a committee of hix memoers of parameter and six members of the Working Men's Association. The principal points of the Charter were—1. That every male inhabitant of the United Kingdom 21 years of age and of same mind, provided he be a native of these age and of sahe mind, provided ne is native of these realins, or have lived upwards of two years in the country and been naturalized, and be unconvicted of felony, shall be entitled to vote in the election of mem-bers of parliament; 2, that the United Kingdom be divided into 300 electoral districts, so as to give uniform

his services. There is nothing contained in the charter that had not been advanced and advocated before. early as 1780 the duke of Richmond introduced a bill early as 1780 the duke of Monmond introduced a full into the House of Lords for annual parliaments and universal suffrage. Unfortunately the majority of the Chartists did not confine themselves to the points of the Charter. Many of them advocated an entire redistribution of property. Ignorant of the principles of political economy, they demanded the establishment of a new relationship between capital and labour, and adopted the cry of "A fair day's wages for a fair day's work." Many of them, further, took up the view that they might, if necessary, employ physical force to obtain their ends. In May, 1839, a petition, signed by 1,280,000 persons, was presented to parliament in favour of the Charter, and during that year serious riots took place in various parts of the country, and various of the ringleaders were imprisoned. An outbreak at Newport, in the month of November, resulted in the death of ten persons and the wounding of many more; and three of the leaders, Frost, Williams, and Jones, were sentenced to death; but their punishment was afterwards commuted to banishment. The stringent meaning and the second of the sentence and the second of the sentence and the sen the Charter. Many of them advocated an entire rewas afterwards commuted to banishment. The stringent measures adopted by the government at length served to repress these violent commotions; and though, in 1842, and again in 1849, outbreaks took place, these were of a less serious nature, and were speedily put down. Chartism may now be said to be a contraction of the contraction of belong rather to the past than to the present, and those who are in favour of the principles of the Charter are who are in avour of the principles of the context we content to advocate their views in a peaceable manner. In nothing is the social progress of the country more marked than in the great change that has taken place in the character of the working classes within the last

quarter of a century.

CHARTREUSE, LA GRANDE, shar-trewz', the chief monastery of the Carthusian order in France. It was founded by Bruno of Cologne, at Grenoble, in 1084. Expelled during the Revolution, the monks

returned to their monastery in 1814.

CHARTULARY, tshort-tu-litere (Lat. chartularia), ori-ginally denoted a collection of charters, and was afterwards applied to the books in monasteries, &c., in which such charters were entered. These books were common even as early as the 10th century, and they have been of great service in historical and genealogical rescarches. The officer who was intrusted with the care of the charters was also called chartulary.

CHASE, tshaise (Aug.-Nor.), is a franchise granted by the crown to a subject, empovering the latter to keep, for his diversion, within a certain precinct so called, the wild animals of chase (which, in a legal sense, are the wild animais of chase (which, in a legal sense, are the same with those to which the right of forcest ex-tends); but not an horizing the establishment of forest law within such precinct. It has been described as, "a smaller forest in the hands of a subject, but not governed by the forest laws." It differs from a park in that it is not inclosed, and likewise in that a man may have a chase in another man's ground as well as in his own: being, indeed, the liberty of keeping of beasts of chase or royal game therein, protected even from the owners of the land, with a power of hunting them

Champin, tshus-e-dim' (Heb., Pietista), is a name given collectively to a whole class of Jewish sects, but, more strictly, it is applied to a modern sect which sprang up in Poland towards the middle of last century. Chasidim and Zadikim were the names employed to designate the two great divisions of the Jewish people which arose after the Babylonish captivity; the former being in favour of certain innovations in the law of Moses, the latter being for a strict adherence to the law as it stood. From the former arose all those naw as it stood. From the former arose all those sects that receive traditions and explanations in addition to the law of Moses, as the Pharisees; to the latter belong the Sadducees, Essenes, &c. Of the modern sect of Chasidim, the founder was one Israel Baalsham, a Jewish rabbi. He gave himself out as having the true knowledge of the sacred name, through which he was andward with miscaulous rowsers and which he was endowed with miraculous powers, and constituencies of about 20,000 voters each; 3. that the voting be by ballot; 4. that a new purliament be elected annually; 5. that no property qualification be required for members of parliament; and 6. that every votes. This sect is very numerous in Poland, Rummember be paid £500 a year out of the public treasury for gary, the Danubian principalities, and Turkey.

CHASING, taked sing (from Fr. enchases), a term employed to denote the art of working raised or halfraised figures in gold, silver, and other metals. distinguished from soulpture and carving, which refer to the same art when applied to marble, ivory, wood, &c. Silver is the metal which has always been most generally used for chasing.

CHASSEROT RIFLE, shase'-po, is a breech-loading rifle and the principal arm of the French infantry. On the recommendation of Marshal Niel, minister of war in 1866, the arm was given out in the September of that year, as an experiment, to the battalion of Foot Chasseurs of the Guard. Its distribution to the other regiments of the Guard only commenced at the close of March, 1807; and, by degrees, as the manu-facture advanced, the delivery of these rifles was ex-tended to the infantry of the line, the whole of which was supplied in little more than a year from the first From the outset the weapon was regarded by the French army and the military authorities as most efficient. At the outbreak of the Franco-Prussian war, the French were firmly imbued with the notion way to the needle-gun of the enemy. The two arms fairly contrasted, the Chassepot is, perhaps, superior in some respects to the needle-gun; but whatever advantages were possessed by the former over the latter, were counterbalanced by the superior steadiness and skill of the Germans. The regulation range of the Chassepot is 1,000 metres, although it may easily extend to 1,100. The projectile, fired at a velocity of 450 mètres per second, has a passage so low, that at a distance of 230 mètres the ball does not rise much a distance of 230 literes the ban does not rise much above the line of aim, which result is a most favour, able condition for the efficacy of fire. From the rapidity with which the arm may be loaded in any position—kneeling, scated, lying down, as well as standing,—the men are able to fire seven, eight, or even ten shots per minute, taking aim, or fourteen without shouldering the gun. With the old musket the maximum range was but 600 metres, the velocity 324 mètres per second; and the men under normal conditions were only able to fire two shots per minute, whilst, as they are forced to load standing, they were all the time exposed to the enemy. With respect to precision of aim, the advantages are not less remarkable. Experiments made show that, in good hands, the Chassepot is a first-class arm; but, in the late struggle, we have seen the natural advantages of the weapon sacrificed through the unsteadiness, the hurry French army in general. The weapon is named after its inventor, M. Antoine-Alphonse Chassepot, head its inventor, M. Antoine-Alphonse Chassepot, head viewer of military arms in Paris. The mechanism of the breech parts consists of the breech, the breech bolt, the movable needle-guide, the holding and re-leasing apparatus for effecting the discharge of the gun, the coiled spring, the needle-holder or head, and the needle. At the right-hand side of the breech there is an opening to permit of the introduction of the cartridge. The mechanism for holding back the needle consists of two small pieces, a lever and a catch, connected together by a screw, and acted upon by a spring. By a simple arrangement, pressure from the trigger is transmitted to the catch, and thereby the releasing of certain parts effected, the result being that the colled spring is brought to act upon the needle. A breech-bolt serves to open and close the chamber to allow of the insertion of a cartridge. A chamber to allow of the insertion of a cartridge. A knob, or handle, on this bolt serves for moving it. The arm is loaded as follows:—The index finger is placed behind the guard, and the thumb upon a raised ronghened portion. The main- or top-piece of the releasing apparatus is drawn back, together with parts immediately connected therewith. To open the arm, the knob or handle of the breech-bolt is turned from the total the part of the described the second of the procedule of the procedule of the place of the place of the procedule of the place right to left, and the bolt then drawn back; then a right to lett, and the bolt then drawn back; then a cartridge is placed in the barrel by the opening at the right of the breech. To close the arm, the breech-bolt is pushed forward, and its knob or handle re-turned from left to right. In order to put the piece in the safety-notch after the breech has been closed, it is necessary, by turning the knob, to place the releasing apparatus in relation with the smaller of two longitudinal slots of the bolt, then to move the re-

#### Chattels

leasing apparatus until its serew reaches the hostonic this slot. When it is required to fire the gun, it is only necessary to close the bolt entinely and to pull the trigger. The Chassepot cartridge consists of air parts, —viz., the priming, the powder-case, the powder, the pasteboard wad, the ball-case, and the ball. The priming consists of a copper cap, like the ordinary military cap, but of smaller dimensions. In the bottom there are two holes dimensions. tom there are two holes diametrically opposite each other, for giving passage to the spark. The fulminating powder is placed at the bottom of the cap. A small plug of cloth or wax covers it, so as to preserve it from outward blows. The cap is then covered with a thin washer of brass or other suitable material, which is pasted upon paper for forming the base of the cartridge, and the priming is thus complete. The powder-case is formed from a rectangular piece of paper, rolled upon a mandrel, and pasted at its edges. When the case is dry, the priming is inserted by a mandrel, after which the end of the case is pasted. mandrel, after which the end of the case is passed. The case being thus prepared, the charge of powder is inserted, and is pushed down gently to give rigidity to the cartridge. A pusteboard wad is next placed on the powder; it is formed with a hole, into which the twisted end of the paper of the case is inserted, the excess paper being cut off. The ball-case is composed of a paper jacket, rolled twice round a conical mandrel and pasted at the base only. After placing the ball in its case, this case is connected with the powdercase by a string or thread round a groove on each case, a slight distance behind the wad. Finally, the cartridge is greased. The reduced size and weight of the Chassepot bullet enables a soldier to take the field with 90 rounds of ammunition, as compared with 60 rounds of the old muzzle-loader rifle.—Ref. The Mechanics' Magazine, vol. xvii.

CHASSEURS, shas'-surs (Fr. chasseur, a huntsman), a name given by the Freuch to bodies of light infantry which act as skirmishers and sharpshooters. They correspond pretty closely with our own 60th regiment, or rifle brigade. The name was originally given by the French to some troops raised in 1815, in imitation of the jügers of the Austrian army, who were chiefly chamois-hunters of the Tyrol, and unerring marksmen as well as active and althetic mountainers. The French chasseurs were of two kinds,—cavalry and infantry; but now the term is more particularly applied to a body of men called Chasseurs de Fincennes, who were carolled and armed with rifles about 1835, and quartered at Vincennes. The chasseurs of the Sardinian army are called Bersaglieri. In the Crimes, the bersagileri of the Sardinian contingent attracted con-siderable attention on account of their activity and peculiar dress, which is soldierly in appearance although easy and comfortable. Garibaldi's chassaurs, that fook a prominent part in the war between France and Sardinia on the one side, and Austria on the other, in 1859, and the campaign against Francis II. of Naples, in 1860, are known as Cacciatori dei Alpi, or Alpine hunters.

CHASURLE, tshus' u-bl (Lat. easula, or presula), the outer dress formerly worn by the priest at the altar, and it seems to have succeeded the Roman togs. It was a circular piece of cloth, with a hole in the centre to admit the head, and it fell down so as to completely cover the body of the wearer. It is not now used in the English church, though prescribed in the rubric of Edward VI.'s First Book to be worn indifferently with the cope. It often appears on the older sculptures and brasses.

and orasses.

Chateau, shit-o' (Fr. château, Lat. castellum, a castel), a term formerly applied to the fortified residences of the French seigneurs. It is now generally applied to the large and more sumptuous country residences of the aristocracy. The word enters into the composition of the names of many towns and districts in Tanana. tricts in France.

CHATELS, ishāu-tels (Old Fr. catals, catels; chatels, movables of any kind), is a term used to express any kind of property which, having regard either to the subject-matter or the quantity of interest therein, is not freehold. The appellation was originally derived from the technical Latis word catalla, which, among the Normans, primarily signified only beasts of huabandry, or, as we still call them, cattle; but, in a

secondary sense, was applicable to all movables in general; and not only to these, but to whatever was not a fief or fend; to which, among the Normans, there were two requisites,—a given duration as to time, and immobility with regard to place. And it is in this latter more extended and negative sense that our own law adopts the term, considering as a chattel whatever amounts not to freehold, which, like the Morman flef, requires immovability in respect of the subject-matter, and a given degree of duration, that is, a duration for a life at least, either absolute or detypinable on a contingency, as regards the quantity of interest or estate. Any estate in lands and tenements which amounts not to freehold, is, consequently, a chattel; but inasmuch as it concerns, or, according to the technical expression, savours of the realty, it is denominated a chattel real, in order to distinguish it from things which have no concern with the realty, viz., mere movables, and the rights connected with

viz., mere movales, and the rights connected with them; and such things as these are, on the other hand, often described as chattels personal.

Calvica, tshāv.e.kd, in Bot., a gen. of plants belonging to the nat. ord. Piperacca, the Pepper fam. The dried unripe spikes of C. Rorburghii constitute the long pepper of commerce, which is imported from our Indian possessions; those of C. officinarum form the lower present used in America, character from the long pepper used in America, obtained from the long pepper used in America, obtained from the Dutch colonies. Long pepper contains an acrid resin, a volatile oil, and a peculiar crystalline alkaloid called Piperine. It resembles black pepper (see Piper) in its effects, and is used for similar purposes. Dried alices of the root and stem are employed medicinally in India under the name of Pippula Moola. Other species of this genus as C. chala under the and valvative. anus under the name of Pipputa Moola. Other spe-cies of this genus, as C. chaba, pepuloides, and sylvatica, have similar properties, and are used in India. The leaves of C. Betle, betel-pepper, and C. Siriboa are ohewed by the Malays and other Rastern races with slices of the betel-nut and lime. (See Betel.)

CHECKMARE. (See CHESS.)
CHEEKMARE. (See CHESS.)
CHEEKMARE. (Sax. cese, or cyse).—Cheese is the
curd of milk salted, pressed, and dried. Milk is
composed of three parls,—the oily or fatty portion, commonly known as cream, and which separates on standing, being lighter than the rest, and the curd, which remains dissolved in the whey until it is coagulated by some soid. In the manufacture of cheese, the ourd is supplied by the reunet, which, being the dried stomach of the calf, contains a large amount of gastric juice, and appears to be the natural milk-curdle. It is prepared by salting and drying the inner membrane of the atomach of a sucking calf. When required for use, a piece is soaked for some hours in water or whey, and the whole added to the warm milk that is to be curdled. When the curd has coagulated, it is sepacurdled. When the curd has coagulated, it is separated from the whey by straining, and pressed in a ring or hoop, from which it is continually removed and wiped to remove all superfluous whey. The colour of English cheese is due to arnotto, which is added to the milk before coagulation. Bath cream and Yorkshire cheeses are soft, and keep but a short time; Stilton is intermediate; and Cheshire, Gloucestershire, and Parkshire, the desire of the control o mesan are hard, and intended for long keeping. The variety of colour and flavour in cheese results from difference of pressure, length of time in keeping, varying proportion of salt, and many other circumstances.

CHEESE-HOPPER, CHEESE-JUMPER, or CHEESE-FLY. -In Nat. Hist., a name applied to a small black insect of the Beetle tribe, with whitish wings, margined with black. It is furnished with an admirable instrument for depositing its eggs in an ovipositor, which it can thrust out and extend to a great length, so that it can penetrate to a considerable depth into the cracks of cheese, where it lays its eggs, two hundred and fifty-six in number. The magget is provided with a couple ax in number. The maggot is provided with a couple of horny, claw-shaped mandibles, which it makes use of, both for digging into the cheese and for moving itself, being destitute of feet. By bending itself into a circle, it can lesp to a considerable distance. In Oglivie's Imperial Dictionary may be seen a drawing of the fly and the maggot.

Of the my and the maggot.

CHEGOR, or CHIGOR, thkey-o (Pulex penetrans), a their component parts.—Spectrum Analysis, which is small black flea, peculiar to South America and the their component parts.—Spectrum Analysis, which is must be composed to the recognition of elementary substances by means of certain lines in the prismatic spectrum of a lamp, in the English flea, it becomes a mild and inoffensive the flame of which their compounds are burnt. See

insect beside the terrible chegoe, which is not only troublesome, but dangerous. This insect burrows in and under the skin, and there deposite its eggs, the result being the most painful ulcers. Waterfor this us that on the plantations of Guines an old woman, known as "Granny," is specially retained to mind the little children, and keep down the chegoe. Every evening she examines their feet (the part generally attacked), and after grubbing out any chegoe she may find, rubs into the hole lime-juice and cayenne peoper.

pepper.
CHEIBOMANCY, OF CHIROMANCY, ki'-ro-man-se (Gr. cheir, the hand; manteia, divination), divination by the hand; the art or practice of attempting to foretell events, or to discover the disposition of a person, by inspecting the lines and lineaments of his hand.

CHEIROMYS, ki'-ro-mis, the scientific name of the Aye-aye. (See Aye-aye.)

CHEIROPTERA, ki-rop-te-ra (Gr. cheir, the hand, and pteron, wing), in Nat. Hist., an animal whose anterior toes are connected by a membrane, and whose feet thus serve for wings, as is the case with the bat. The animals which belong to this wing handed family are such as are comprised in the Vespertilio of Linuwus. They are capable of sustained flight, and are distinguished by a folding extension of the membranous skin, which, rising from the sides of the neck, is spread between their fore feet and their flagers.

18 spread between their fore teet and their lugers.
Chenorisativit, ki-ro-the're-um. The German naturalist Kaup refers to the footprints of a mammiferous animal found in the old red sandstone of Hildburghausen under this title. To the same origin many similar remains in England have been referred. Professor Owen is of opinion that the animal was reptilian. In all probability it was a batrachian rep-

reptilian. In all probability it was a batrachian reptile. The footprints occur with ripple-marks on the flaggy red sandstones of the Mersey, and also in Dumfriesshire.—Ref. Eng. Cyclo.—Nat. Hist. CHEIROSTEMON, ki-vos-te'-mon (Gr. cheir, the hand; stemon, a stamen), in Bot., a gen. of trees of the nat. ord. Stereutiance. The species C. platonoides is the Handplant of Mexico, which derives its common name from the remerkable superspace of its flowers: the authers the remarkable appearance of its flowers; the anthers and style being so arranged as to resemble a hand fur-

nished with long claws.

CHELIDONIUM, kel-i-do'-ni-um (from Gr. chelidon, a swallow, the plant being said to flower at the coming, and dry up at the departure of the swallow), in Bot., the Celandine, a gen. of plants belonging to the nat. ord. Papaveraceæ. The species C. majus is found in waste places and on old walls in this country, and may waste places and not waste in this country, and may be recognized by its small reliow flowers, and the orange-coloured juice which exudes from its stem when plucked. This juice is poisonous, and is a popular application for the cure of warts. It has been used with success in the treatment of opacities of the cornea,

and has been administered internally as a stimulant. CHELIFER, kel'-i-fer, in Nat. Hist., a genus of arachnida, bearing a close resemblance to acorpions. These remarkable animals are very small, and have the appearance of miniature tailless scorpions. They run rocks by the seaside. They also find a location in the They also find a location in the barks of trees, and among papers and old furniture in houses. They feed upon insects, and are met with in all parts of Europe.—Ref. Eng. Cyclo.—Nat. Hist. CHELONIA, kc-lo'-nc-ü (Gr. chelonia, a tortoise), in Nat. Hist., the numerous and highly interesting order of reptiles in which are comprised the tortoises and the turtles. (New Torgards.)

the turtles. (See TORTOISE.)
CHEMICAL ANALYSIS, kem'-i-kül.—For theoretical information on this subject, see ANALYSIS. The pracitical portions of it are treated under the heads of Dialysis, which is the separation of crystalline and non-crystalline constituents of solutions by means of non-crystalline constituents of solutions by means of the intervention of an absorbing disphragm; —Inorganic Analysis, the detection and separation of the constituents of products not being either of an animal or vegetable nature; —Organic Analysis, which is the resolution of animal and vegetable substances into their component parts; —Spectrum Analysis, which is the recognition of elementary substances by means of cartain lives in the primatic spectrum of a lamm. In

elso Qualitative Analysis, which is the accurate de-tection of the components of a substance without reference to their proportions;—Quantitative Analysis, the separation and weighing of the constituents of a compound; — Volumetric Analysis, the quantitative estima-tion of the component parts by means of measured test solutions of a uniform strength. (Consult also BLOW-FIFS and RE-AGENT.) The best text-books on these subjects are enumerated at the end of each article.

CHEMICAL ATTRACTION. (See AFFINITY.)
CHEMICAL FORMULE.—The alchemists, for the sake of mystery, employed the signs of the different planets to represent the various metals. Modern chemists, for the sake of convenience and brevity, have given to every element one or two letters called symbols, which are used, in conjunction with figures and algebraic signs, to express every known compound. (For the symbols of the different elements, see SYMBOLS.) The principle apon which modern chemical notation is founded, is that each symbol indicates one or more atoms of the element it represents: thus, C, C<sub>a</sub>, C<sub>a</sub>, indicate respectively one, two, and twenty-seven atoms of carbon. Two symbols, placed side by side, signify that they are in close chemical union: thus, AgO signifies a com-pound containing an atom of silver united to an atom of oxygen. A comma, separating two or more groups of symbols, must be taken to mean that they are not in such intimate chemical union that the groups cannot be separated without decomposition: thus AgO, NO, represents nitrate of silver, which, by certain treatment, can be separated into AgO, oxide of silver, and NO<sub>5</sub>, nitric acid. The sign plus + signifies that the union is still weaker: thus, AgO, NO<sub>5</sub> + HO means nitrate of silver united to an atom of water, HO. A number placed on the left of a group of symbols sigor plus, is to be multiplied by it: thus, KO,2CrO, signifies that one equivalent of potash is united with two of chromic acid. Sometimes the group to be multiplied is inclosed in a parenthesis:  $3(\text{HgCy}) + 2(\text{KO}, \text{SO}_s)$ means that three equivalents of cyanide of mercury are united to two of sulphate of potash. Formulæ may be empirical or rational,—the former giving merely the constituents of a compound, the latter indicating the manner in which they are grouped. It is evident, therefore, that a compound can only have one empirical formula, while its rational formulæ are as numerous as the theories of its composition. Alcohol, for instance, is represented empirically by the formula CAH<sub>3</sub>O<sub>2</sub>. Rationally, it may be represented as the chylate of water, HO,C<sub>4</sub>H<sub>3</sub>O; the hydrated oxide of ethyl, C<sub>4</sub>H<sub>4</sub>O, HO; as a compound of olefiant gas and two equivalents of water, 2HO,C<sub>4</sub>H<sub>3</sub>, and so on, ad infinitum. Brackets are used to denote substitution compounds; that is, compounds in which one element, or group of elements, has been substituted for another without materially affecting the character of the compound.

NH: H represents ammonia. NH represents platinamine, or ammonia in which

an atom of platinum has replaced an atom of hydrogen. In like manner,

 $\left. egin{array}{c} \mathbf{H} \\ \mathbf{H} \\ \mathbf{C_4H_8} \end{array} \right\}$  is the formula of ethylamine, or ammonia with

an atom of hydrogen, replaced by an atom of ethyl. Two changes have been lately introduced into chemical formulæ that it will be well to notice;—one in which dashes are used to denote the atomic power of the element; the other, a line through a symbol, to signify that its atomic number has been doubled. Bi''' means that bismuth has a tristomic power in the way of forming substitution compounds: thus,

N.H. H. Bi''' is an ammonia compound in which three

equivalents of hydrogen are replaced by one of bismuth, that metal having a triple uniting power. This

## Chemical Nomenclature

notation originated with M. Gerhardt, an eminen French chemist, whose views on the subject are daily gaining ground, and are fully explained under the head of Gerhard's Notation. Chemical Nomenclatures.—The present system of

chemical nomenclature is due to the immortal Lavoisier. and will ever remain a monument to his marvellous powers of systematic classification. It is based on the great principle that the name of a compound should, as far as possible, express its composition and proper-ties. The names of many of the simple elements we have received from the alchemists, and were formed on no definite plan. Those elements which have been lately discovered have been named either from some characteristic property possessed by them, or from some word indicating their source. Metals, as a rule, terminate in ium, as potassium, thallium, &c.; metaloids in on, as boron, silicon, &c.; gases in one or gen, such as chlorine and oxygen. In several instances theory grounded on insufficient facts has been allowed. to influence the name of an element; for example, oxygen was named from oxus, acid, and gennae, to generate; the Lavoisierian theory being that no acid could exist without oxygen. Subsequently, however, it was found that oxygen occurred in all bases, and that many acids existed that contained hydrogen in its The Lavoisierian nomenclature is founded on stead. the fact that when a compound of two elements is submitted to the action of the voltaic current, these being attracted by the negative pole, and the other (electro-negative body) going to the positive pole. As a rule, it was found that the metalloids were electro-negative and the metalloids were electro-negative and the metalloids represented the metalloids were electro-negative and the metalloids represented the metalloids were electro-negative and the metalloids represented the metalloids were electro-negative. combinations of two elements are termed binary compounds, and fall naturally into two divisions,—bases and acids. Bases always end in ide, and are compounds of different proportions of a metal with a metalloid. The proportion of the metalloid is indicated by the addition of a Greek or Latin numerical particle: thus we have the protoxide, sesquioxide, binovide, and ter-oxide of various metals, indicating that these com-pounds contain one, one and a half, two, and three doses of oxygen to one of metal. When the metal is to excess, Greek prefixes are used: we have, for instance, the dinoxide or trisoxide of a metal, showing that the metal is in a double or triple dose. Generally the prefixes sub and per are used to indicate the excess of metal over metalloid, and vice verad. The termination used in several cases, such as sulphuret, phosphuret, &c.; but it is now abandoned in favour of the termination ide. The compounds of the metalloids with each other are named on the same metalloids with each other are named on the same metalloids with each other are named on the same principle. When the dose of oxygen is large, the compound is generally possessed of acid properties: thus we have Cr<sub>2</sub>O<sub>3</sub>, the sesquioxide of chromium, which is a base; but, by increasing the oxygen, we obtain CrO<sub>3</sub>, which is an acid capable of forming salts with bases. The amount of oxygen contained in oxygen, which is a superior of the oxygen oxygen of the oxygen oxygen of the oxygen oxygen of the oxygen ox acids is indicated by the termination to or our, or the prefixes hypo, under, or hyper, above. A few examples of bases and acids will illustrate this:—

Pb.,O	Dinoxide or suboxide of lead. Protoxide or oxide of copper.
Fe.O	Sesquioxide of iron.
MnO	Binoxide of manganese.
AuO <sub>3</sub>	Teroxide of gold. Pentachloride of phosphorus.
PS	Dodecasulphide of phosphorus.
C10	Hypochlorous acid,
NO	Nitrous acid.
NO <sub>5</sub>	Hypochloric acid Nitric acid.

Certain metalloids, such as sulphur and hydrogen, combine with other metalloids to form acids: for instance, we have-

HC1	Hydrochloric acid.
HRe	Hydrobromic acid.
A . Q	Sulpharsenic acid.

The compounds of acids with bases are always indicated by the termination or prefix of the word giving the name of the acid. Acids ending in our and to form sales

**R 3** 

## Chemical Nomenclature

ending is ite and ate, the prefix being, of course, pre-served. A few examples of this will suffice:—

Sulphate of iron = sulphuric acid + oxide of iron Hypophosphate of lead = hypophosphoric acid +

oxide of lead. Sulphate of copper = sulphurous acid + oxide of

copper.

Hyposulphate of cobalt = hyposulphurous acid +
oxide of cobalt.

When the oxide with which the acid is united is a pro-When the oxide with which the acid is united is a protoxide or peroxide, the prefixes proto and per are added; for instance, the pernitrate and protonitrate are the nitrates of the protoxide and peroxide of the metal. When the dose of acid is greater or less than the base, the prefixes sub, sesqui, bi, are used; as the subcarbonate, bicarbonate, and sesquicarbonate of soda. In double salts the name of the base only is repeated; as the tartrate of potash and soda. There are a few the tartrate of potash and soda. There are a few instances of acids and salts which have the same composition, but different properties. They are dis-tinguished from the ordinary kind by the prefix meta; thus we have phosphoric acid and metaphosphoric acid. The prefix pyro signifies that the acid or salt has been obtained by heat; for instance, we have pyrogallic acid, produced in this way from gallic acid. In organic chemistry the nomenclature is in many cases somewhat confused. This is not owing to any want of proper principle in the formation of new words, but rather to the differences of opinion existing amongst rather to the differences of opinion existing amongs chemists as to the composition of the substances indicated. Thus anilino is cylled phenylamine, phenylia, and benzidam, by different chemists, who each have a theory touching its composition. Organic chemistry may be defined as the chemistry of organic radicles or compounds containing carbon, which act in every way as elements. Organic radicles generally terminate in yl, and mostly contain carbon, hydrogen, and oxygen. Thus we have ethyl, the radicle of ether, which forms oxides and salts in the same manner as iron, lead, or any of the purely elementary bodies. (See Organic Transport of the process of RADICLES.) There are also compounds corresponding to the electro-negative bodies oxygen, hydrogen, nitrogen, &c. We have, for instance, cyanogen and amidogen, which form cyanides and amides, similar in their properties to chlorides and oxides. The termination of or ole is generally applied to neutral compounds of carbon ole is generally applied to neutral compounds of carbon and hydrogen, possessed of neither basic nor acid properties, and are mostly liquids; such as bensol, pyrol, quinol. The termination in is applied to other neutral substances, generally solid; such as paraffin, maphthalin, and albumin. Those ending in ine or in are generally bodies allied to the alkalies in their properties. We have, for instance, quinnine or quinning strychnine or strychnia, aniline, &c., which form salts with acids. Many of those which end in anine resemble ammonia, and are considered substitution resemble ammonis, and are considered substitution compounds of that body, in which one or more equivalents of hydrogen are replaced by an organic radicle. Thus we have ethylamine (Ethyl)C.H.

N, in which one equivalent of hydrogen is replaced by one of ethyl. If two or three equiva-lents are replaced, the prefix di or tri is added to the word; for instance, we have dimethylamine and triword; for instance, we have amentycamine and repropylamine, the composition of which is plainly indicated by their names. When the hydrogen is replaced by different bodies, their names are prefixed. We have, for instance, ethyl-methyl-amylamine, which consists of one equivalent of nitrogen united to one sach of the organic radicles ethyl, methyl, and amyl. There are also substitution acids as well as bases; such as brombeneoic acid and chloracetic acid, in which bromise and chlorine are substituted for an equivalent of hydrogen. Thus, although these names appear unintelligible and unwieldy to the superficial observer, they are as easily understood by the chemical student as any term including several nouns and adjectives would be to an ordinary individual. In this respect chemical nomenclature bears a very fiscourable contrast with that belonging to mineralogy and bottomy, the sciences being disfigured by the introduction of the principles of which the substances black art, were at any rate its most ardent wetaries. each of the organic radicles ethyl, methyl, and amyl.

## Chemistry, History of

are called after their discoverers, or some great man whom the discoverer wishes to flatter, instead of bear-

ing names indicative of their proporties or origin.

CHEMIST AND DRUGGIST, kem'-ist, a term commonly applied to any person who has been apprentised to, or regularly educated by, a vendor of drugs or dispenser of medicines, but who does not set as a visiting apothecary or surgeon. In this country the chemists and druggists constitute a very important and useful class. They sell medicaments, simple, or compounded ac-cording to the prescriptions of medical men; and they also act as medical advisers for the benefit of the poorer classes. The right of chemists and druggists to prescribe even in the manner usually followed in what is called "counter-practice," has been often questioned by the literary organs of the medical profession; but the highest legal authorities declare that they may so far prescribe for customers as to advise with them as to the nature and author and authority and an organization. to the nature, and quality, and mode of application of the medicines which they are about to sell; that they may listen to the statements of the customers, and may suggest to them and recommend the commodities which will be suitable and beneficial, or dissuade them from purchasing or taking things applied for in ignorance. The advice given by the chemist and druggest is merely incidental to the sale and dispensing of his wares and drugs, and cannot, of course, be made the subject of a charge. Counter-practice has always been a recognized branch of the business of the chemist and druggist, and we do not find it prohibited by any clause in the Apotheoaries Act of 1815; on the contrary, we read that "all persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same trade or business in such manner, and as fully and amply to all intents and purposes, as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this act." Two societies have been established by the members of the trade; viz., the Pharmaceutical Society of Great Britain and the United Society of Great Britain and the United Society of Chemists and Druggists. The objects of each will be noticed under its title.

CHRMISTRY, HISTORY OF, kem-is-tre (Arab. kimia, the occult science; Fr. chimie, Ital. chimica).—There is, perhaps, no science the gradual progress of which is is, pernaps, no science the gradual progress of which is so easily traced from one step to another as the science of chemistry. The empirical mixing of two substances, possessing different properties, to form a third, differ-ing from either, must have commenced with the first peopling of the earth. The fact was transmitted to others who improved as it as the second control of the second contr others, who improved on it, and experimented on other similar bodies; and thus was a mass of practical information obtained, which gradually developed into chemical manufactures. The origin of chemistry is generally traced to Tubal Cain, the father of workers in metal, between whom and Hermes Trismegistus lies a period of obscurity of which we know nothing. Hermes is said to have been the inventor of alchemy, a notion not entitled to much credit. In any case, Egypt, which is said to have been colonized by his son Mizvaim, was the foremost chemical nation of the East; their glass, pottery, colours, and method of embalming their dead, bearing strong testimony to the fact of their being acquainted with chemical processes brought to a peng acquainted with chemical processes brought to a great state of perfection. The practical part of the science existed provious to the theoretical; but by degrees, as men began to think, they began also to-observe and theorize. Thinking men saw that a gross earthy matter, such as iron ore, became transmuted, as it were, by fire into a hard metallic substance, like What more rational, then, for them to suppose

Chemistry, History of Gradually, another notion stole in. The principles and practice of pharmacy became more general, and a specious logic was brought to bear on the fact that specious logic was brought to, hear on the fact that centain salts and liquors of a metallic nature assuaged pain and restored drooping vitality. It was then but one step further to go to find a compound that would prolong life indefinitely. Another object of pursuit was the universal solvent, or alkahest. The first practisers of alchemy were, no doubt, honest, serious men; but as time wore on, there arose a mass of impostors who found need dupos in available of the ware. who found ready dupes in avaricious people, who were ver ready to buy the secret of unbounded riches. this way there was formed a mass of almost unintel-ligible knowledge, carefully concealed from the vulgar by secret symbols and an absurd nomenclature. Through this accumulation of rubbish there ran some golden this accumulation of rubbist bleed an arms govern-veins; and we must never forget, that although al-chemy had its philosophers' stone and universal sol-vent, it also gave us a hundred salts and preparations daily used in our own laboratories. Towards the end of the 17th century arose a set of men whose brains were made in a better mould than those of their predecessors. Putting aside the idea of transmutation of metals, they turned their attention to the discovery of the principles that governed the formation and composition of bodies already in their hands, rather than to the pur-suit of chemical chimeras that might for ever clude their grasp. Paracolsus, though imbued with the fanciful doctrines of astrology and demonology, must always be regarded with reverence for his virtues and pity for his faults. He must ever be considered as the connecting link between the alchemists and chemists. A few of his researches will be sufficient to show that although full of the maddest hallucinations, he was one of those rare geniuses who have the power of lifting a science from the mire. He was the first to offer a true chemical explanation of the action of mercury, iron, and lead in the human system. He distinguished slum from copperas, showing that the former contained an earth, the latter a metal. He admitted the existence of other clastic fluids besides air. He was aware that animals could not live, and inflammable matters could not burn, without air. To him succeeded Van Helmont. who was the first to distinguish between acrial fluids or gases, as he called them. After Van Helmont came Boyle, the founder of the Royal Society, one of the most acute experimentalists that ever lived. His numerous experiments are marvels of accuracy, bearing even the test of our present knowledge. He and his contemporary Hook made great improvements in the air-pump, the invention of Otto Guericke, and paved the way to further discoveries. At the beginning of the 18th century come the names and discoveries of Beecher and Stahl, the founders of the phlogistic theory. They found that by heating charcoal with metallic oxides or calces, they were reduced to a me-tallic state. They further noticed, that when charcoal tallic state. They further noticed, that when charcoal was burnt it was entirely dissipated. Upon these was built in was distributed with the car to fear the facts they founded the theory that charcoal, or phlogiston, was a principle which united with the car to form the metal. This notion appeared to be further carried out by the fact that metals, when heated, are carried out by the fact that metals, when heated, are converted into calces; the explanation of which was, that the volatilized charcoal, or phlogiston, was consumed by the heat. This theory, which was the first general principle applied to the whole range of chemical phenomena, maintained its ground for some time, until the discoveries of Priestley tended to overthrow it, by proving that the calx, or oxide, of mer-cury, instead of gaining something by being heated, lost something, and that that something was oxygen. lost something, and that that something was oxygen. About this time Cavendish discovered hydrogen, and Rutherford nitrogen, experiment being heaped on experiment, and discovery on discovery, until the Stahlian theory gave way. It was succeeded by that of Lavoisier, the father of modern chemical science, who classified and arranged the known chemical facts into a system unparalleled for its precision, extent of view, and logical accuracy. His discoveries were few, but he reasoned on the discoveries of others with wonderful astuteness. From this moment chemistry marched onward with giant strides. It would be impossible to enumerate the whole of the discoveries that have taken place since the commencement of the present who classified and arranged the known chemical science, light of the facts disclosed in the investigation of the row and logical accuracy. His discoveries were few, but he reasoned on the discoveries of others with wonderful astuteness. From this moment chemistry is to obtain a good elementary manual, such wonderful astuteness. From this moment chemistry marched onward with giant strides. It would be imposmatched on a great properties of organic matter. (See Organic and Information of the properties of organic matter. (See Organic matter.) when the properties of organic matter. (See Organic matter. (See Organic matter.) when the properties of organic matter. (See Organic matter. science has progressed even in our own time. The application of the voltage current to the decomposition application of the voltaic current to the decomposition of the alkalies, by Davy, resulted in the discovery of a dozen or more new metals. The atomic theory of Dalton threw great light upon the composition of salts and acids. The invention of the present symbolic notation by Berzelius, and the determination of the elementary equivalents soon followed. In 1811 Davy worthwart he notice of Lavisia that a light Davy overthrew the notion of Lavoisier, that soids could not exist without oxygen, by proving that hydroculorio acid consisted only of chlorine and hydrogen. In 1812 Courtois discovered iodine; Balard followed soure time after with bromine. Element succeeded element until atter with bromine. Element succeeded element until they reached the number of sixty. All this time organic chemistry was making great progress. The vegetable alkaloids began to attract great stention; their analyses were made, and new theories founded on them. The early labourers, Liebig and Berzelius, threw great light on this branch of the science, which is even to this day the most attractive to many famous chemists. The development of the many famous chemists. The development of the theory of organic radicles has gone on increasing, fostered by the labours of Paraday, Laurent, Gerhardt, Hofmann, and a host of others, until it has assumed a mathematical precision unknown to any other branch of physical science. The investigations of organic mathematical precision unknown to any other branch of physical science. The invostigations of organic compounds by these philosophers have resulted in a complete change, both in the notation and nomenolature of mineral substances. This theory, which was founded by Gerhardt, will be fully explained under Gerhardts Theory. The last great discoveries have been spectral analysis, which has resulted in the addition of these new slavagets unkny list. tion of three new elements to our already bulky list;cesium and rubidium, by Mesers. Bunsen and Kirch-hoff, of Heidelberg, and thallium, by Mr. Crookes, a distinguished English analytical chemist. The researches of Graham upon the diffusion of salts in solution and in dialysis, or the separation of crystallizable and noncrystallizable substances in solution by means of an intervening displursm, are amongst the most brilliant discoveries of the age. The researches of Schönbein, Schroetter, Brodie, and others, on the allotropic states of bodies, seem to point to the compound character of the present elementary bodies. In fact, chemistry at the present day is making such enormous strides, that it can only be properly studied in the current scientific journals.

CHEMISTRY, PRINCIPLES OF.—Chemistry has been variously defined by different philosophers; that of Miller (Elements of Chemistry, vol. i.) being perhaps about the best;—"It is the province of chemistry to ascertain the nature of the different substances of which the universe is compassed to these their meters of the different substances of which the universe is composed, to trace their mutual reactions on each other, to effect new combinations of these components with each other, and to define the conditions on which the combinations existing around us are producible." The world and its inhabitants are us are producible." The world and its inhabitants are made up of some sixty-five elements or bodies, which have hitherto proved undecomposable. Their general description will be found under ELEMENTS; their particular description under their respective heads. The combinations of these bodies are described under BASES, SALTS, ACIDS, RADICLES; while the general laws which regulate their composition will be found under ATOMIC NUMBERS, AFFINITS, SRIES, TYPES, ATLOGRADIAN ISMORPHISM. ISOMERISM, POLYMOR-ALLOTROPISM, ISOMORPHISM, ISOMERISM, POLYMOR-PHISM, &c. Inorganic chemistry treats of the nature and properties of elements and compounds of mineral and properties of elements and compounds of mineral origin, and organic chemistry of those belonging to bodies of a vegetable or animal nature. The long-existing barrier between the two is, however, being gradually destroyed by the labours of Laurent, Gerhardt, Hofmann, Wartz, Odling, and others, whose brilliant discoveries prove every day more and more that we must read the chemistry of the rocks by the light of the facts disclosed in the investigation of the light of the facts disclosed in the investigation of the

much less expensive than those necessary for analysis, which is, after all, the highest branch of chemical menipulation. Besides this, in performing synthetical operations, the student insensibly acquires manipulation, and in addition finds himself, at the end of a few months, in the possession of a vast number of interesting specimens, which will serve for material when he finds himself capable of performing elementary analysis; whereas the results of analysis are generally thrown away. The best books for the chemical student are perhaps the following, the order indicating the sequence in which they should be read:—Fownes' Rudi-mentary Chemistry, Bernay's First Steps; Fownes' Manual; Odling's Manual. The latter is an exposition of the unitary system of Gerhardt.

Chemistry, as a fruited to Agriculture.—The object of the practical farmer is to raise the largest quantity of valuable produce from a given extent of land at the smallest cost, in the shortest period of time, and with the least permanent injury to the soil. Until recently, agriculturists endeavoured to attain these results by experiment and experience; it has, however, been demonstrated, that chemistry, geology, and chemical physiology, point out clearly the proper steps by which the main object may be effected. Agricultural chemistry, as a science, collects, investigates, and endeavours to explain all known facts in practical hasbandry. It also deduces principles from observation and experiments made in the field or the laboratory, which may be more or less applicable in all circumstances. With a knowledge of such principles the farmer can understand symptoms and appearances he has never before seen, and can adapt his practice to circumstances which have never before fallen under his observation. Agricultural chemistry also suggests improvements, and, probably, unthought-of modes of rendering the soil fertile, besides inducing the analysis of soils, manures, and vegetable products. Chemical physiology also explains how plants grow and are nourished, and how animals are supported and most cheaply fed.—Ref. Elements of Agricultural Chemistry and Geology, by J. F. W. Johnston.

CHENOTODIACEE, ke-no-po-de-ai'-se-e (Gr. chen, a goose; pous, a foot), iu Bot., the Goosefoot or Spinach am, a nat. ord. of diootyledonous plants, in the subclass Monochlamydea. There are 72 genera, which include 510 known species, distributed over all parts of the globe, but most abundant in extra-tropical regious,—herbs or undershrubs, with leaves without stipules, alternate, or, rarely, opposite; flowers minute, greenish, without bracts, perfect, polygamous or dichnous; calyx persistent, usually divided nearly to the base, imbricated; stamens usually equal in number to the lobes of the calyx, and opposite to them: overy superior or partly inferior, 1-celled, with a single ovule attached to its base, and a style usually in 2-4 divisions, rarely simple. Fruit an schænium or utricle, or sometimes baccate. Several plants of this order inhabit salt-marshes, and yield by combustion the sodals called barilla (which see). Many are esculent; as beet and mangold-wurzel (see Bern), spinach (Spinacia disrace), garden orach (Atriptex hortensis), and English mercury. (See Chenofodium). The seeds of there are nutritious. Several contain volatile oil, which renders them anthelmintic, antispasmodic, aromatic activates and stimular.

which renders them anthelmintic, antispasmodic, aromatic, carminative, and stimulant.

CHENCODIUM, ke-no-po'-de-um, in Bot., the typical gen. of the nat. ord. Chenopodiacea. The seeds of C. Quisoa contain; starch granules, which are remarkable for being the smallest hitherto noticed. They are known under the name of petty rice, and form a constant of the contains article of food in Peru. C. honus Henricus is the lish mercury, a plant formerly much used as a pottish mercury, a plant formerly much used as a pottish mercury, and in North America for their anthelmintic and antispasmodic properties. C. rulearia stinking goosefoot), an indigenous plant, is a popular stinking goosefoot, an indigenous plant, is a popular summenagogue. C. ambrosioides is employed in Mexico and Columbia as tea; hence it is commonly known as Mexican tea.

Mexican tea.

O'Mexican tea.

O'

whom a cheque is drawn is obliged to honour it if he has funds belonging to the drawer in hand. Until dishonoured, it must be regarded as payment. An ordinary cheque is made payable to a certain person or bearer. For purposes of safety and convenience the use of cross-cheques has been introduced. Two transverse lines are drawn across the cheque, and the words "& Co." are written between them. Payment of a cross-cheque can only be procured by passing it through another bank.

through another bank. OHERINGYER, ker-e-moi'-er, the name commonly given to the fruit of the Anona cherimolia. It has been described as the finest of all fruits, and is generally esten for dessert by the wealthy inhabitants of Peru and Brazil. It is sometimes called the cherimolia. (See Anona.)

(See ANONA.)
CHEREY and CHEREY LAUEEL. (See CERASUS.)
CHEREY and CHEREY LAUEEL. (See CERASUS.)
CHEREY, tsher'-ub (Heb., plural cherubim, mighty ones), the name of a particular order of angelic beings frequently mentioned in Scripture. They were placed with flaming swords to guard the garden of Eden when Adam and Eve were driven out of it; and when Moses was commanded to make the ark of the covenant, he was to place a cherub on each end of it, so as to cover the meror-seat with their wings. What the form was under which the cherub was here represented we have no certain account, and various conjectures have been thrown out on the subject. Many are of opinion that, as in Ezekiel's vision, it was composed of parts of aman, lion, ox, and engle. In art, cherubs are commonly represented by a child's head with wings, or as a human figure with wings at the shoulders, and wings also in place of the lower extremities.

place of the lower extremities.
CHENYIL. (See ANTHRISCUS.)
CHENS, takes (Fr. &ckees), an ingenious and intellectual game, played by two persons, each having at command sixteen pieces, made of wood, bone, or ivory, upon a board divided into sixty-lour squares, eight on each of the four sides. These squares are coloured red and white, or black and white, alternately, and the pieces of each player are of different colours. On either side there are eight superior pieces and eight inferior. The former consist of a king. a queen, two bishops, two knights, and two rooks or castles; the latter consist of eight pawns, or foot-soldiers. On commencing a game, the king and queen occupy the commencing a game, the king and queen occupy the centre squares of the first or royal line, and are supported in regular succession by a bishop, a knight, and a rook, while before each piece stands a pawn. In placing the board, it is always the custom, in this country, to place a white square at the player's righthand corner; and, in arranging the pieces, the queen is always placed on a square of her own colour. The pieces on the king's side are called the king's,—as king's bishop, king sknight; while those on the queen's side are similarly styled queen's bishop, &c. The pawns take their names from the pieces before which they stand; as, the king's pawn, king's rook's pawn, queen's pawn, &c. Every superior and inferior piece moves according to certain rules, and the success of the game depends entirely upon skill. A knowledge of the varied moves is acquired over the chess-board with comparative ease from any competent person. The queen is the most powerful piece on the board, while the king, from the nature of the game, which does not admit of his exchange or capture, is the most important piece; the game depends upon his safety by a competent authority as,—queen, 9.94; rook's 48; bishop, 3:50; kinght, 3:05; pswn, 1:00. Towards the conclusion of a game, however, the pawn rises in value. When the king is directly stracked by any piece or

Chaturanga, or the four members of an army; namely, elephants, horsemen, chariots, and foot-soldiers. Since that time the game has undergone many alterations. It passed into Persia from Hindostan, and then into It passed into Persia from Hindostan, and then into Arabia, where it was called Shatrang, or the king's distress. In the 8th century the Arabs introduced the game into Spain, and from thence it passed into the rest of Europe. Chess was unknown to the ancient Greeks and Romans, but it was played in England before the Norman conquest. The Eastern game differs in several peculiar points from the game played in Europe, but resembles the game played by the Saxons. The laws of chess are at present undecided and practiferatory. The hest books of reference are Saxons. The laws of chees are at present understand unsatisfactory.—The best books of reference are Staunton's Chess-player's Handbook, and Morphy's Games at Chess, edited by Lowenthal.

CHEST, in Anat. (See TRORAX.)

CHEST, MILITARY and NAVAL, tsheet (Sax. cist or cyst).—The term Military Chest is applied to the money

and securities which are held by the chief of the com missariat department during a campaign, to provide pay and provisions for the soldiers. The Naval Chest, or Chest at Greenwich, as it is sometimes called, is a fund to provide for the necessities of sailors who are unable to pursue their calling in consequence of any injury. Gratuities and pensions for a certain number of years, or for life, are given out of this fund. It was originated in the reign of Queen Elizabeth, the sailors voluntarily giving up a small part of their monthly pay to form the fund. The money thus obtained was de-posited in a chest kept for the purpose; whence the

CHESTNUT. (See CASTANEA.) CHETAH, OF HUNTING LEOPARD. (See LEOPARD.)

CREVALUER. (See CHIVALER)
CHEVALUE DE FRIER, shee'-o de freez' (Fr., horses of Friesland), long beams of wood or iron, bristling with spikes, that are passed through the beam at regular intervals, in alternate directions, at right angles to each They are used to defend the ditch or berme of any fortification during an attack, and to impede the advance of a storming party when entering a breach. These implements of warfare are easily carried with an These implements of warfare are easily carried with an army, and, in our service, consist of hollow cylinders of iron, about six feet long, pierced to receive the spikes or pickets, which are carried in the interior of the cylinder when the army is on the march. The origin of the name is uncertain; but it was probably first used by the Dutch during their protracted but successful struggle against Philip II. of Spain in the 16th century. 16th century.

CHEVRON, shev'-ron (Fr. chevron), in Her., one of the nine honourable ordinaries, occupying a third part of the field. It represents the raiters of a house, and shows that the person to whom the coat of arms in which it occurs was first granted, was the founder of his family, or had achieved some important and honourable undertaking. The diminutives of the chevron are the chevronel and the couple close.—In Arch., it is a zigzag moulding, a peculiar characteristic of Norman architecture.

CHEVEOUS, in Mil., stripes worn on the arm to dis-tinguish the various grades of non-commissioned officers. The sergeant-major wears four stripes, serjeants three, corporals two, and lance-corporals one. Light infantry, the light and grenadier companies of all regiments, and the guards and fusiliers, wenr the stripes on both arms. They are composed of gold lace surpes on rotal arms. They are composed of gold lace or white braid in the regular army; but in the volunteer service anything is allowed except gold lace. The stripes are worn with the point downwards, above the elbow, and are thus distinguishable from good-conduct stripes, which are worn with the point upwards below the albow. the elbow

CHEVY CHASE, tshev'-e-tshais, the name of one of the CHEVY CHASE, takev-c-takois, the name of one of the most famous of the old English ballads, narrating a hostile encounter that took place on the Scottish border between the two warlike families of Percy and Douglas. Percy, earl of Northumberland, had vowed to hunt for three days in the Scottish border without condescending to ask leave from Earl Douglas. He had with him 1,500 men, and Douglas brought against them 2,000. In the middle of the contest the two earls meet hand to hand. After fighting for some time, Douglas is pierced to the heart by an English arrow,

and Percy immediately after falls by a Scottish spear. Although the leaders were thus both sisin, the battle still reged with great fury, till only 53 of the English still raged with great fury, till only 53 of the Bragish and 55 of the Scottish remained. The event referred to in the ballad, though apparently different from the battle of Otterbourn, which took place in 1338, is probably the same, or at least the tragical circumstances attending the latter have been incorporated in it. The beauties of this balled have been criticised by Addison in the "Spectator" (Nos. 70 and 74); and Sir Philip Sidney said of it, that he never heard the old song of Peroy and Douglas but his heart was more moved than we at truncet. These greater was song of this balled as by a trumpet. There are two versions of this ballad, an ancient and a more modern, both of which are given in Percy's "Reliques of Ancient English Poetry."

in Percy's "Reliques of Ancient English Poetry."
CHIRO-OSCURO, or CHIROSOUGA, ke-ar'-o-a-ku'-ro, ke-ar'-o-a-ku'-ro (Ital. chiaro, light; oscuro, dark), that branch of painting which has for its object the combination and arrangement of the light and dark parts of a picture to the best advantage. Relief and depth, and what is generally called the effect of a picture, are produced by ohisrosouro. Leonardo de Vinci was the first who reduced the art of chiaroscuro to a system. Correggio aftorwards improved it practically; and it is said to have reached perfection under Titian. is said to have reached perfection under Titian. CHICA, a red dye. (See BIGNONIA.)

CHICA, OF MAIZE-BEER. (See ZEA.)

CHICKEN-POX, tshik'-en-pox, in Med., is the name given to an eruptive disease, usually of a mild nature, and bearing some resemblance to small-pox. Some are of opinion that it is only a mild form of small-pox, but it is generally regarded as a distinct disease. It is mostly confined to children, and is of a contagious mostly conuncd to children, and is of a contagious nature. The premonitory fever is very slight, and the vesicles are filled with a watery fluid, rarely with yellow matter or pus, and pass away in the course of four or five days, leaving only slight crusts or scales, which fall off without leaving any permanent mark. The disease is rarely attended with danger, and, generally, all that is necessary is to put the patient upon spare diet, and to administer a dose or two of some mild aperient.

CHICK-PRAL (SOC COURE)

to administer a dose or two of some mild aperient.

CHICK-PEAL (See CICER.)

CHICK-WEED. (See STELLARIA.)

CHICORY. (See CICENCHIM.)

CHIEF, tsheef (Fr. chef, from Gr. kephale, the head),
denotes the highest in office or rank, the head or principal part of anything.

CHEF, in Her., one of the nine honourable ordinaries, occupying the upper part of the shield and a third part of the field. When any charge or charges are borne in the upper part of the field, they are said to be in chief.

CHIEF JUSTICES, tsheef just tis (Fr. chef, chief; Low

CHIEF JUSTICES, tsheef just-tis (Fr. chef, chief; Low Lat. justiciarius, justice), are the principal judges of the courts of Queen's Bench and Common Pleas; the chief judge of the court of Exchequer being called the Lord Chief Baron. (See JUDGES.)

CHIEFTAIN, tsheef-tām (Old Fr. chefetain, from chef, chief), is the leader, captain, or chief of a troop, army, or clan, but generally of the last. The chieftains of the Highland clans of Scotland were the patriarchal and feudal heads of their respective clans. (See CLANS)

CHILBLAIN, tshil'-blain (Ang.-Sax.chill, cold; blain, a pustule or blister), is an inflammatory affection of the skin, occasioned by exposure to sudden alternations of heat and cold, and usually affecting the hands or feet. Young persons are more subject to it than adults, and females than males. The partis red and swollen, and is attended with heat and a great sense of itching. Chilblains are generally produced by persons holding their hands or fect to the fire immediately after they have been exposed to great cold. This is to be darefully guarded against, and a uniform temperature, as far as possible, nuaintained by the use of warm socks and gloves. The itching is best removed by frequently rubbing the part with some stimulating application, as camphorated spirits of wine. One of the best means of removing chilblains on the hands we have found to be washing them nightly before going to bed with warm water, which allays the heat and promotes the general circulation. If the parts should ulcerate, it is often very difficult to heat; but the best application to use is spermacht in others. attended with heat and a great sense of itching. Chil-

CHILDEBMAS-DAY, OF INNOCENTS' DAY, takil-der-

mas (Ang.-Sar.), an anniversary of the Church of England, held on the 18th of December, in com-memoration of the children of Bethlehem, slain by order of Herod.

Children, kil'-li-dists (Gr. chilius, a thousand), in Bool. Hist., was applied to those who believed that Christ was to come again and reign a thousand years (See MILLENIUM.) upon earth.

CHILLAD SHOT. (See SHOT.)
CHILLABS. (See CAPSICUM.)
CHILLERN HUNDREDS, tshill-tern hun dreds, is a portion of Buck-inghesmahire known as the Chiltern Hills. The stewardship of the Chiltern Hundreds is a nominal office under the crown, in the chequer, and serves the purpose of enabling a member of the House of Commons to resign his seat (which he cannot do unless in some way disqualified), it being regarded as a place of honour and trust under the crown. The office is resigned immediately afterwards.

CHIMES, tslames (Dan. kimer, to tinkle), a peal of musical bells placed in a church-tower, and either rung by hand or by machinery con-trived for the purpose. In the ordinary art of bell-ringing, melody is never thought of, mechanical order and succession are the only results simed at. In Belgium and Holland there are some very perfect

chimes.

CHIMNEY, tshim'-ne, the flue for conveying away the smoke of fires. The term is derived immediately from the French chemine, the feminine form of chemin, used to convey the idea of a narrow passe; but primarily the derivation is from the Latin caminus. A chimney, besides being an agent for the removal of smoke, also assists in the combustion of the fire by producing a draught. Simple as is the contrivance of a chimney, it was unknown in ancient times. Tomlinson considers that they were in use in England at some time previous to 1368; but the use of the curfew bell in preceding centuries indicates their absence, as the people were thus summoned to cover the fires that burned in pits in the centre of the floor, under an opening in the roof. That they were in common use in Venice during the 14th century we gather from the fact that a number of them were thrown down by the earthquake which occurred in that city in the year 1347. In England only in the year 1997. In Enganne, however, they were not in general use even as late as the time of Queen Elizabeth, when they were still only huxuries to be met with in the houses of the great. Nicholson, in nonnes of the great. Nicholson, in his Dictionary of Architecture, thus designates the various parts of a chimney and of the wall in which it is inserted:—"The opening facing the room, where the fire is put, is termed the fire-place: the stone, termed the pre-place; the sounce is called the hearth; that on the same level before the fire-place is termed the stab. The vertical sides of the opening, at the extremities of the hearth forming also ment of

Fig. 2. SECTION.

the hearth, forming also part of the wall of the apartment, are called jambs; the heart of the fire-place resting on the jambs, is apartment, and forms the sides of the funnel pare-called the mantel; the wholeshollow, from the fire-place to the top of the wall, is denominated the wall, the side of the funnel opposite the breast is 494

called the back. When there are two or more chimcalled the back. When there are two or more chimneys in the same wall, the divisions between them, or the solid parts of brick, stone, or metal, are called miths. A gable, partition, or party-wall containing a collection of chimneys, is termed a stack of chimneys. The turret above the roof, for discharging the smoke into the air of one, two, or a collection of chimneys, is called the chimneys. And it, and the horizontal surface, or the upper part of the said shalft, the chimneytop. When the parallel sides of the jambs are fixed with stone, marble, or metal, so as to form four obtuse top. When the paramet suce of the james at the with stone, marble, or metal, so as to form four obtuse angles, viz., two internally with the back, and two externally with the breast or side of the apartment, making the horizontal dimension of the outside of the fire-place of greater extension than that of the back, the facings are called corings." With regard to engine and factory chimneys, we are informed that the celebrated Montgolfier, the inventor of the fireballoon, was the first to examine the general principles of chimney-draughts, as applied in manufacturing establishments. Dr. Ure made a series of interesting and valuable experiments respecting the velocity of and valuable experiments respecting the velocity of air in large chimneys—in the breweries of Messrs. Tra-man, Hanbury, & Buxton, and at the machine-factory of Messrs. Braithwaite, and elsewhere, the results of which are to be found in the 6th edition of Ure's Dict. of Arts, Manufactures, and Mines. The limits which are to be found in the 6th edition of Ure's Dict. of Arts, Munipactures, and Mines. The limits of this work preclude our enlarging upon this department of the subject of chimneys. We may, however, quote one portion of Dr. Ure's account of his researches:—"In building chimneys, we should be careful to make their area rather too large than too small, because we can readily reduce it to any desired size by means of a sliding register-plate near its bottom, or a damper plate applied to its top, adjustible by wires or chains passing over pulleys. Wide chimby wires or chains passing over pulleys. Wide chimneys are not so liable as narrow ones to have their draught affected by strong winds. In a factory many furnace-flues are often conducted into one vertical chimney-stack, with great economy in the list erection, and increased power of draught in the several fires." Mr. Hirst, of the Office of Works, Whitehall, has invented and patented a new method of constructing chimney flues and tunnels, which has been tried, and found to succeed in many public buildings. The plan consists in building within the usual walls, and plan consists in building within the dustal wails, and incorporated with the common brickwork, circular smoke-flues or tunnels, which are surrounded in every direction, from top to bottom, by cavities, or bot-air chambers, commencing at the back of each fire-place, and connected with each other. The air confined within these chambers is said to be rendered sufficiently warm by the heat of any one fire, to prevent condensation in all the flues contained in the same condensation in all the flues contained in the same stack of chimneys. The figure of each brick composing these circular flues is wedge-like, their inclined figure enabling the builder to construct chimneys which may be curved and carried in any direction without producing any internal angles, the bricks being readily adapted to any required curvature. To construct a straight flue the thick ends of one course of bricks are placed alternately upon the thin ends of the next course; and, in order to make curves, the thick ends are placed together on one side. From the construction of these chimneys, and the nature of the materials of which they consist, no danger need the materials of which they consist, no danger need be apprehended should the soot ignite, for large accumulations of soot cannot take place, there being no internal ledges for it to rest upon. At the Saint Rollox chemical works, near Glasgow, there was a chimney—in Scotland called a "stalk"— not less than 450 feet from foundations to summit. The diameter 450 feet from foundations to summit, at the top 13 feet upon the ground-line was 40 feet, at the top 13 feet 6 inches. At Musprat's soda-seh factory, near Liver-6 inches. At Muspratt's soda-san factory, near Liverpool, there was a chimney 406 feet high; the dismeterat the ground-line was 46 feet, and at the top 9 feet. At the Rdinburgh gasworks there is a chimney 341 feet 6 inches in height. In 1859 a most ingenious device for straightening a chimney-stalk was conceived by Mr. Duncan Macfarlane, architect. The colossal chimney at Port Dundas had swayed to a considerable degree out of the perpendicular. In order to render this straighten at straight and safe. Mr. Macfarlane ordered agreeoutor the perpendicular. In order to render this structure straight and safe, Mr. Macfarlane ordered several of the mortar beds between the courses, on the side frem which the chimney leaned, to be sawed; there-

by allowing it to some back by its own weight, without the application of any external force. Only one direct cut at a time, to guard against any shock, which might have endangered the stability of the building; and by keeping the saws wet, a bed of mortar was prepare for the superincumbent weight to settle dow In this manner twelve cuts were made upon different parts of the structure, which generally set before the saws had passed through half of the circumference; saws and passed through that of the circumference, particularly in those made nearest the ground, where the weight was greatest. The method was attended with complete success. The principal dimensions of this chimney are—height, 468 feet; outside diameter, at foundation 50 feet, at surface 34 feet, at cope 14 feet. In 1861, MM, De Sanges and Masson addressed to the Feeth Andreas of Sanges and Masson addressed. to the French Academy of Sciences a paper regarding a novel mode of arranging chimneys. uniting all the flues in one place, so that the smoke passes into a single chamber, or receiver, near the roof of the house, and from which the smoke escapes by an opening at the top of the chamber in its centre. The system has been tried, with satisfactory results. Eight flues opening into a single chamber, and used Eight flues opening into a single chamber, and used singly, or two, three, or more at a time, and with wood, coal, and coke, have been used for eighteen months, and the draught has been very regular under all circumstances. These tall chimneys are built to convey away the noxious fumes from chemical and manufacturing establishments, and so relieve the neighbourhood of the nuisance they would otherwise convict. occasion. These immense structures are built up from a solid base, with side flues leading into the central cavity. The size of this cavity should, as in the chimneys of dwelling-houses, be of rather larger area than the sum of that of the flues which lead into it. In large stacks it varies from 3 feet in diameter, or 3 feet square, to 6 feet, contracting gradually towards the top. They are constructed with a brick for 3 feet square, to 6 feet, contracting granuary flowards the top. They are constructed with a brick lining, so laid as to leave an air-space between it and the outer wall, the effect of this being to check the rapid dispersion of the warmth of the vapoure. According to the Civil Engineers' Journal, vol. will. p. 319, the dimensions of tall chimneys should be sa

CHIMPARED this man and Communication. The annexed drawings exhibit the elevation and trans-

pentag by Robert Good Burn.
CHIMPANZER, thim-pan-zee (Troglodytes niger), so species of ape, and one which in form and structure exhibits the greatest resemblance to man. It is a native of the warmest parts of Africa, and seldom attains a beight exceeding four feet when in an erect receiving. Its skin is thickly account with large black. position. Its skin is thickly covered with long black hair in front; and on the head, back, and limbs the hair grows thicker than elsewhere. The ears are thin, prominent, and naked, and not unlike human ears in shape. The appearance of the nasal organ is that of a mere pucker in the skin. The thumb of the hand is smape. The appearance of the based open the hand is amer pucker in the skin. The thumb of the hand is small and weak; that of the foot remarkably large and powerful. One of the most important of the distinctive points of difference between the anatomy of man and the anthropomorphous apes, is that in the former the muscle which terminates in a single tendon and concentrates its action on the great toe, in the case of the apes the same muscle terminates in three tendons, none of which is connected with the great

## China-ware

toe or hinder thumb, but which flex the three middle toes,—part of the adaptation of a foot for clasping as a hand. The great toe of the chimpansee is shorter than the other toes, and opposed to them as a thumb. The most man-like of this genus, however, is undoubtedly the gorilla, about which, till within the last quarter of a century, searcely anything beyond the most vague and preposterous stories were known. The chimpansee differs from the ourang-outang in having a cranium broader in proportion to its face, in eight more minute distinctions as to the characteristics of the skull; in the smaller size of the interistics of the skull; in the smaller size of the inceristics of the akult; in the smaller size of the incisor and canine teeth, and inferior development of the jaws, giving it a more human and less beast-like head; and in many other points relative to the conformation of the chest, loins, fingers, &c., amounting Professor. altogether to twenty points of difference. Professor Owen considers that, from the structure of the jaws and dental system of the ourang-outang, which are scarcely inferior to those of the lion, and greatly resemble those of the fiercer and more terrible carnivors, the chimpanzee ought to take place above the ourang-outang, and not below it, as it does in the Asimal Kingdom of Curier. It has often been stated that these animals are apt at imitating human habits, that these animals are apt at imitating human mouts, and of acting with gentleness and docility. Such statements must be received with caution. Whilst still young, they often exhibit great docility; but as they grow old, they become sullen, savage, and ferocious, and, like the rest of the anthropomorphous apes, are irreclaimably vicious. (See GORILLA,

OTHAMS-OTTIMES, AFE.)
CHINA-WARK. (See PORCELAIN POTTERY.)
CHINCHILLA, tshin-tshil-td, a small rodent animal, chiefly valuable for its fur, which is beautifully soft, down, and of considerable length, but so loosely attached to the abin. That it falls off unless handled with tached to the skin, that it falls off unless handled with considerable care. It associates in numbers, and excavates burrows, in which it resides, feeding chiefly on roots. In size and general form it resembles the rabbit, excepting the tail, which curls over, after the fashion of the squirrel's. It is a native of South America, and inhabits the valleys of the high mountain-districts. The length of the body is about nine inches, and that of the tail five. As soon as they die, their bair falls off; and for this reason it is unavailable for many purposes to which otherwise it would be

applied. CHINESE ARCHITECTURE, tshi'-neze .- The architecture of the Chinese is peculiar to China, differing entirely in form and ornamentation from that of any other Eastern nation. The materials that are used in building consist chiefly of marble, stone, wood, brick, bamboo, and tiles of porcelain, which are glazed and coloured. The erection of all buildings in China, whether for public or private purposes, is carried on under the supervision of a surveyor; and the rank of the person who is to inhabit it has much to do with the form and size of the private dwelling-house. These consist principally of a ground-floor and first floor; but houses of many floors have been sometimes built, reaching 200 feet in height. A great quantity of wood is used in building, which is richly coloured and relieved with gilding, so that the houses present a gay and picturesque appearance. The walls of the apments on the ground-floor are of tolerable solidity, generally pierced with square or long and narrow windows, which are often filled with elaborate trellis-On these walls wooden columns are erected to support the roof, which is formed of bamboo, and for the most part turned up at the edges. sometimes made in two parts, resembling one roof raing out of another. The windows and doors are often circular in form. The walls are plastered and decorated with panels containing paintings and inscriptions in the Chinese symbolic characters. Balconies are generally formed in front of the apartments on the first floor, the front of which consists of trellis-work. The royal palaces are of great extent, consisting of a series of courts, with galleries and halls of sudience, beautifully painted. The last court in the series is set spart as the residence of the em-

# Chinese Language

which was plundered by the French and burnt by the British in 1880, was surrounded by pleasure-grounds filled with heautiful buildings devoted to various purposes. Their tombs and mansoleums are generally formed in the side of a hill, the entrance being in the centre of a wall of polished granite, built in the form of a horseshoe, and flanked with side-walls surmounted by a heavy coping: a platform of granite is generally placed before the entrance. Arches of wood or stone are often erected across streets or at the entrance to a town or dwelling-house, with an inscription to the memory of some person deceased. Their temples differ greatly in form and size, but in many points of architectural construction and decoration they re-semble the dwelling-houses of a higher class. The ordinary temples, or joss-houses, consist of a chamber containing an idol. The Buddhist temples are larger and more elaborate, consisting of a vestibule, which leads to courts containing temples, sometimes two stories in height, in which are seated colossal images of Buddha. Buildings for various purposes are at-tached, such as the reception of animals offered by worshippers of Buddha, and the ashes of the priests who are burnt after death. The courts are surrounded by colonnades, behind which are rooms or cells, in which the officiating priests of the temple reside. The pagodas, which form a conspicuous feature in Chinese scenery, are either monumental records, or are in-tended for the reception of some relie of Buddha, are either monumental records, or are inlike the Japanese temple Boro Buddor. They are like the Japanese temple noro nugaror. They are generally octagonal in form and nine stories in height, surmounted by a conical roof, from which an ornamented pole rises. Each story is less in size than the one below it, and is surrounded by a balcony, from which a sort of pent-house projects, ornamented with bells at the corners. These pagodas are built of brick, and the exterior of some of them is coated with porcelain tiles. The walls of their cities are high, and broad at the top, with square towers at intervals. Their castles are also square in form, being contracted in size towards the top, and surmounted, like the walls, with battlements. The Chinese build bridges with circular, pointed, and elliptic arches, and assert that the method of constructing the various forms of arches has been known to them from very early ages, which is doubtful. Mr. Robert Scott Burn, in his useful work on architectural design, observes: "Every detail of Chinese archidesign, observes: "Every detail of Chinese archi-tecture is under strict supervision, and there is no deviation from established rules, which dictate the size of a house according to the rank or status of the occupant. Chinese columns have no capitals; the shaft is shaped like the frustum of a cone, the height varying from eight to twelve times the diameter at its lowest part. The base is formed of a square plinth, with, in some instances, a moulding above it. A pole, which some instances, a monitong above it. A pois, when is passed through an aperture at the upper end of the shaft, corresponds to the architrave in classical architecture; this is supported by two brackets, the lower part of which is inserted in the shaft. These are sometimes ornamented. A series of panels placed cometimes ornamented. A series of panels placed above this corresponds to the frieze, ornaments being painted in the spaces between the panels. The whole is surmounted by the concave tent-like roof, the angles of which being turned up, are ornamented at their extremities by representations of the heads of dragons."—Ref. Encyclo, Metropolitana and Huc's Travels in Tartury, Thibet, and China.
CHINESE GRASS. (See BCHMERIA).
CHINESE LANGIAGEA AND LIEVEN ADDRY—The Chinasa

CHINESE GRASS. (See BCHMERIA.) CHINESE LANGUAGE AND LITERATURE.—The Chinese language belongs to that class of tongues of Eastern Asia that are commonly termed monosyllabic, i.e. in which each word is pronounced by a single movement of the organs of speech, and each expresses a com-plete idea or object. The words all terminate either in a vowel or diphthong, or a nasal sound. Of such words or roots there are about 450 in the language. Many of these words, however, are differently pronounced or accentuated,—some of them in four or five different ways, and having as many different meanings. In this halls of sudience, beautifully painted. The last court in the series is set spart as the residence of the embout 1,200. There are, besides, many words that, with the same pronunciation, express very different things, about 1,060 yards in length by 840 yards in breadth. The words undergo no changes of form, and the want the words undergo no changes of form, and the want has Yuen-ming-yuen, or Summer Palace, near Pekin,

498

or by the position of the words in a sentence. construction of the sentence is thus an important part of Chinese grammar, as upon it the meaning mainly depends. There are numerous dialects of the Chinese; but it is said to be spoken most purely and correctly at Nankin. The best grammars and dictionaries of the Chinese language are those of Morrison and Medhurst. In Chinese the alphabet is not composed of letters, but each word has a certain character peculiar to itself; and hence the number of characters corresponds with the number of words in the language. As the same words differently pronounced express different objects, the number of written characters must necessarily correspond; and hence it is said that the number of characters in the language exceeds 40,000. In its origin the Chinese language is hieroglyphic or pictorial, and to the original characters a number of symbolical and conventional signs have been added; by the union of which ventional signs have been added; by the union of which hieroglyphs and symbols, with an imperfect indication of the sound, the greater number of the Chinese characters are composed. Native grammarians divide their characters into six classes; the first comprising simple representations of sensible objects; as the sun, moon, mountain, tree, &c., and including 608 characters. The second class includes such as are formed that the interest the second class includes such as are formed. by the union of two or more simple hieroglyphs, which give a more or less clear idea of the meaning intended to be conveyed; as the sun and moon combined give the idea of light; mouth and bird, that of song. Of this class there are 740 characters. The third class is this class there are 740 characters. The third class is composed of such as indicate a certain relation of place; as above, below, the numerals, &c.,—of which there are 107. The fourth class comprises such chathere are 107. racters as, by being inverted, convey a contrary meaning; as right, left, standing, lying,—and contains 372.

The characters of the lifth class are termed borrowed characters, as expressing abstract ideas or mental acts by means of representations of sensible objects; as a eart signifying the spirit, a room a woman : of these there are 598. The sixth class comprises those that are composed of a hieroglyph and a mark representing the sound. Almost all the names of animals, trees, plants, and many other objects which it would be too difficult to represent hieroglyphically, are indicated in this way: their number is given at 21,810. These, however, are merely repetitions of those of the other five classes; so that the entire number of Chinese characters may be reduced to 2,425; and if one has characters may be reached to know all. Of the great number of characters that are to be found in Chinese dictionaries, amounting to about 40,000, not more than a tenth part are in common use. In the arrangement of their dictionaries, the Chinese select a certain number of characters, usually about 214, which serve as a sort of key, and answer the same purpose as the letters of our alphabet. The Chinese Literature is undunited with a side and in a comment. rature is undoubtedly the richest, and, in a geographical, historical, and ethnographical point of view, it is the most important of the whole of Asia. The printed catalogue of the library of the emperor Kein-long consists of 122 volumes; and a selection of the Chinese sissa of 122 volumes; and a selection of the United Classics, with commentaries and scholia, begun by command of the same mouarch, is said to comprise 130,000 volumes had appeared. In the five canonical or classical books called the "King" are contained the oldest specimens of the "Aing" are contained the onest specimens of Chinese poetry, history, philosophy, and jurisprudence, some portions of which are probably among the oldest written monuments of the human race. They were collected from various sources by Confucins in the 6th century before Christ; and in this collection they have century before Christ; and in this collection they have been handed down to us with apparent fidelity. The five "Kings" are—1. The "Y-king," or Book of Changes (a Latin translation of which was published by Mohl,—Stuttgart, 1832); 2. the "Schu-king," or Book of Annals, which is imperfect, comprising fragments of the early history of the people (Chinese and English, by Medburst,—Shanghai, 1846); 3. "Schi-king," the Book of Songs (in German, by Rückert,—Altona, 1833); 4. "Tschiur-thsien," the History of certain Kingdoms, from 770 B.C. to the time of Confucius; 5. "Li-ki," or Book of Germanies, which coutains a series of laws Book of Ceremonies, which contains a series of laws and directions extending down even to the minutest details of life. The "Tscheu-li," which has been translated into French by Biot (Paris, 1851), is a kind

of official handbook of the old Chinese empire. M the "Kings" in value and importance are the "S schu," or the four books which were written by Con sond, or the lout books and are to be regarded as the most certain sources for information regarding that important school of philosophy which has no marked a manner affected the whole intellectual and political a manner affected the whole intellectual and political condition of the Chinese. These four books are generally known as the works of Confucius, and have been translated into various languages:—into English by Collie (Malacca, 1828). To these books numerous schola, commentaries, and paraphrases have been within. scholia, commentaries, and paraparates and written. Almost contemporary with Confundas was Lac-tse, also the founder of a wide-spread school of philosophy. In mythology they have "The Book of Lactures, also the founder of a wide-spread sensol of philosophy. In mythology they have "The Book of the Mountains and Seas" and the "History of the Gods and Spirits." In jurisprudence, worthy of special notice is the general collection of laws and the original code of the present ruling dynasty—(See "Ta-Tsing-leu-lee, being the fundamental laws and supple-mentary statutes of the penal code of China," by Staunton; London, 1810.) The Chinese literature is also very rich in medical works, and works on natural history, astronomy, uranography, geometry, agri-culture, war, music, and all branches of technology and mechanics.—(See "Résumé des principaux Traites Chinois sur la Culture des Muriers et l'Education des Vers a Soie," by Julien; Paris, 1837.) In philology, the first rank is due to their dictionaries, which have the lirst rank is due to their dictionaries, which nave been prepared with great diligence, and examples col-lected out of the whole treasury of Chinese literature. The greatest work of this kind is the dictionary of the emperor Kang-hi, which is now regarded as the highest authority for the form, pronunciation, and significa-tion of the characters. Equally rich and valuable is tion of the characters. Equally rich and valuable the encyclopædic literature of the Chinese; amou which is the work of Matuan-lin (A.D. 1800), entitled "Wen-hien-thong-khao,"—i.e. an accurate examination of the ancient documents, with rich supplements,—presenting an ingrigatible with rich supplements, presenting an inexhaustible mine of the best materis for a thorough knowledge of the Chinese and the tor a thorough knowledge of the Uniness and was neighbouring races, from the oldest to the most recent times, in every department of life. But the most valuable department of Chinese literature is undoubt-edly the historical and geographical, which are abso-lutely indispensable to a thorough knowledge of Upper Asia. See ma-thsian (B.C. 100) compiled his "Seeki," or Historical Memorials, from every available source, and gives the history of China from B.C. 2837 to the commencement of the dynasty of Han, in the second century before the Christian ers. This work has been continued by the different dynasties, and forms a complete collection of the annals of the empire down to the end of the last dynasty of Ming, A.D. 1643. The entire collection of the official annals from 2698 B.C. to A.D. collection of the official annals from 2008 B.C. to A.D. 1645, a period of 4,343 years, and comprising 3,705 books, is to be found perfect in the library of Munich. Amongst their other labours, the Chinese have by no means neglected poetry, of which there are voluminous collections that have yet to be made known to Europe. As lyric poets, the names of Tu-su and Li-thai-pe, who flowing the labour the 3th actions are according to the contract of the second secon As tyric poets, the names of Tn-su and Li-that-pe, who flourished about the 8th century, are specially ramous. Of their numerous poems little is as yet known.—(See Davis "On the Poetry of the Chinese," in the "Transactions of the Royal Asiatic Society," vol. ii.) The romances of the Chinese are not characterized by any great flights of the imagination, but are valuable as giving an insight into the domestic life, and the modes giving an insignt into the domestic me, and the indees of thinking, feeling, and acting of the people. Their dramatic poetry follows peculiar rules, and approaches partly the romantic plays of the Germans, partly the commedic delle arti of the Italians. They have also a kind of dialogue novels, which form a subordinate spe-cies of drama. The best-known collection of dramas is "Yuen-dschin-pe-tschong,"—i.e. the Hundred Dramas from the Mongolian dynasty (1260—1341), out of which all the dramas that are yet known to us have been all the drames that are yet known to us have been taken; as the "Lac-seng-urh," or an Heir in his Old.
Age, by Davis (London, 1817); "Hang-koung-tsew," or the Sorrows of Han, by Davis (London, 1829). The richest collections of Chinese books in Europe are at Paris, London, Berlin, Munich, and St. Petersburg. We possess as yet no history of Chinese literature. The Chinese themselves have numerous works of this class. but they are very mearre, and are almost each class; but they are very meagre, and are almost en

## Chinese Tallow

tirely confined to bibliographical and critical aketches. Ref. Brockhaus's Co. ratione Lexikon.

CRIMEN TALLOW. (See STILLINGIA.)
CHINGEY, hi-rur-je (Gr. cheir, a band, and ergon, a work), is a term sometimes used in place of surgery, from surgical operations being performed by the hand.

CHIVALRY, tohiv'-dl-re (Fr. chevalerie, from chevalier a haight or horseman), is a term applied to the order of largethood established during the Middle Ages in almost all the kingdoms of Europe, and whose laws, rules, and customs are still to be found largely perrules, and customs are still to be found largely per-vading the manners and oustoms throughout Europe. Though chivalry first assumed importance in the 11th century, it was far from being, as many have supposed, as invention of that period, but sprang naturally and by degrees out of the feudal system that had long prevailed over a great part of Europe. Its origin is to be taxed to the feudal mansions of the barons, where young men were trained to the occupation of the between the vassal and his lord. By degrees the in-fluence of the Church manifested itself, and religious ceremonies were mingled with those by which a young ceremonies were mingled with those by which a young man was adustited to the rank of a warrior. To the influence of the clergy are to be attributed in great measure those high moral principles that characterized the spirit of chivairy, and were so far in advance of the them condition of lay society in general. The coucation of a knight was briefly as follows:—The young and noble stripling, generally about his 12th year, was sent to the court of some baron or knight, where he seemt his time in acquiring the use of arms and atspent his time in acquiring the use of arms and attending upon the ladies. The respect for female character, which was one of the marked features of chivalry, was one of the characteristics of the ancient German tribes, and is mentioned by Tacitus. When advancing age and experience in the use of arms had qualified the page for war, he became an escuyer, or esquire, so called from escu, or scudo, a shield, because it was part of his duty to carry the shield of the knight whom he served. The third and highest rank of chivalry was that of knighthood, which was not conferred before the 21st year, except in the case of dis-tinguished birth or great achievements. The individual prepared himself by confessing, fasting, &c.; religious rites were performed, and then, after promising to be faithful, to protect ladies and orphans, never to lie or utter slander, to live in harmony with his equals, he received the accolede, a slight blow on the neck with the flat of a sword, from the person who dubbed him a the nat of a sword, from the person who dubbed him a hnight, and who, at the same time, pronounced a for-mals to this effect:—"I dub thee knight, in the name of God and St. Michael (or in the name of the Father, Son, and Holy Ghost). Be faithful, bold, and for-turaste." A warlike spirit, an undefinable thirst for glosy, and a lofty devotion to the fair sex, were the great characteristics of chivalry. The crusades gave a more religious turn to the spirit of chivalry, and made the knickts of all Christian nations known to each other. the knights of all Christian nations known to each other. Chively was at its height between the 11th and the 14th centuries. It decayed with the decline of fends institutions, in the 15th century, and in the 16th it had almost ceased to exist.

almost ceased to exist.

CHIORANTHACEE, klo-rün-thai'-sc-e (Gr. chloros, green; anthos, a flower), in Bot., a small nat. ord. of diestyledonous tropical plants, in the sub-class Monocklemydee, consisting of about fifteen species, which are arranged into three geners. They are herbs or under-shrubs, with jointed stems, sheathing leaves, and spiked achiamydeous flowers, with scaly bracts. The typical genus Chloranthus includes some useful apecies. The roots of C. officinalis and brackystochys have been employed in Java ses timulants in malicinant Lave been employed in Java as stimulants in malignant fovers, and for their antispasmodic effects. The leaves of C, inconspicuus are used in China to perfume tea. Aromatic stimulant properties are common to all the plants of this order.

CRICAGE ACID, klor'-ik (ClO<sub>a</sub>).—This acid has never been obtained in an isolated condition, it being, as yet, impossible to separate from it the last equivalent of water. It is formed by passing a current of chlorine through an alkaline solution, when the chloride of the most and the chlorate of the alkali are formed. It is or simed as a monohydrated acid by mixing an equiva-

### Chlorimetry

lent proportion of sulphuric seld with a solution of chlorate of baryta, and submitting the decented liquid to spontaneous evaporation in vacuo. It is colourism, strongly soid, has an oily consistence and a pungent smell. Paper dropped into it inflames. It is not decomposed by light, and its exidizing properties are very powerful. It forms salts with bases, called observers, which are decomposed by heat, the chloride of the metal being left behind, while oxygen is liberated. The most useful of them is the chlorate of potash, which is formed by passing chlorine through a solution of caustic potash: chloride of potash and chloride of potassium are formed, the former being separated by crystallization. (For an account of its valuable pro-

crystallization. (For an account of its valuable properties, see Potash, Chlorate of.)
Chloride of Lime. (See Calcium, Chloride of.)
Chlorides, klor-ides.—Chlorine enters into combination with the metals and the non-metallic elements, forming compounds of great importance. These will be treated of particularly under the heads of their respective bases. They all, however, possess some common properties which it will be well to consider in this place. With the exception of the chloride of silver and the sub-chlorides of mercury and conse silver and the sub-chlorides of mercury and copper, all the chlorides are soluble in water. In many of their properties they closely resemble the oxides; and it is generally found that a metal will enter into as many combinations with chlorine as it does with oxygen. Thus we have the proto- and bi-chloride of platinum, corresponding to the proto- and bin-oxide of that metal. They are all fusible at ordinary temperatures, and melt and dissolve with greater readiness than their corresponding oxides. Chlorides of metals are mostly formed by dissolving the oxide or carbonate of the metal in hydrochloric seid. This process fails in the case of magnesium and aluminium. of the metallic chlorides are decomposed when heated in a current of hydrogen, hydrochloric acid and the pure metal being the result. This is taken advantage of in the formation of pure iron and several other metals. The chlorides of the noble metals are gene-rally decomposed by simple ignition, the metals rerally decomposed by simple ignition, the other maining behind in an uncombined form. The other maining behind in an uncombined form. When heated with black oxide of manganese and sulphuric acid, they eliminate chlorine.

CHLORIMETRY, klor-im'-e-tre (chloriae, and Gr. metron, a measure), the name given to the method of determining the amount of available chlorine in the chloride of lime of commerce. There are several ways of effecting this. The oliest is ascertaining the weight of the amount necessary to decompose a certain amount of a standard solution of indigo or sulphuric amount of a standard sometion or hands and acid. This process has been abandoned, being rendered fallacious from the solution of indigo becoming more analysis discoloured by keeping. The method spontaneously discoloured by keeping. The method at present employed consists in determining the at present employed consists in determining the amount of bleach necessary to convert a known quan-tity of arsenious acid, AsO<sub>3</sub>, into arsenic acid, AsO<sub>3</sub>. Another method, which is perhaps more frequently used than the one just mentioned, is to ascertain the quantity of bleaching-powder which is required to peroxidize a known amount of protosulphate of iron. A certain amount of protosulphate of iron is dissolved in water,-say 50 grains of the latter to 1,000 grains of in water,—say or grains of the latter to all the former, forming the test-liquid. Fifty grains of bleaching-powder are dissolved in a little water and poured into a test-measure. The bleaching-powder poured into a test-measure. The bleaching-powder solution is then dropped into the protosulphate until a drop of ferricyanide of potassium (red prussiate of potash) no longer gives a blue precipitate. The operation is concluded by a simple rule-of-three sum. Chlorimetry is an hourly operation with calico-bleachers, it being important to know the exact strength of the steeping-liquor at each immersion of fabric, Mr. Crum's process is the one generally employed. It is founded on the property possessed by acetic acid of turning a solution of a persalt of iron to a deep red. Known quantities of acetic acid, perchloride of iron, and bleach-liquors are mixed together, and the colour produced is compared with those of twelve vials ranged in a frame, containing similar ingredients, submitted to known but varying proportions of chlorine. In this instance the colour indicates the exact amount of chlorine contained in the measured

#### Chlorine

quantity of bleach liquor; from which data the per-

centage is easily calculated.

Chloring, klor'-ine (Gr. chloros, green),—symbol Cl, equivalent 35-5, spec, grav. 2-44.—Chlorine, dephlogisticated marine acid, or arymuriatic acid, was discovered by Scheele in 1774, while examining an ore of manganese. It was thought at first to be a compound gas; but Gay-Lussac and Themard supposed, and Sir Humphry Davy proved, that it was an elementary body. It was the latter philosopher that bestowed upon it the name of chlorine, from chloros, green (Greek), on account of its colour. It occurs in nature in great abundance, in combination with many mineral but Gay-Lussac and Thenard supposed, and Sir substances, such as rock-salt; also in sea water and sea plants, as the chlorides of potassium and sodium. sea plants, as the chordres of potassian and souther.
It may be prepared in two ways,—either by heating black oxide of manganese with hydrochloric acid, or by heating a mixture of black oxide of manganese, chloride of sodium, and dilute sulphuric acid. It is a caloride of sodium, and difficult to the stransparent gas of a greenish-yellow colour and a powerfully suffocating odour, which, even largely diluted with air, produces great irritation of the airpassages. One hundred cubic inches weigh between 77 and 78 grains. It is, therefore, about two and a half times heavier than atmospheric air. Water absorbs about twice its volume; it can, therefore, be only collected by displacement or over warm water. Under a pressure of four atmospheres it condenses into a yellow limpid liquid, rather heavier than water, and remains fluid and unfrozen at a temperature of -220° Fahr. With water, chloring forms a definite hydrate, which, when subjected to a cold of 32° Fahr., solidifies in the form of large yellow crystals. Chlorine is not combustible, but supports combustion to a cer-tain degree. A wax taper burns in it with a reddish smoky flame, the hydrogen of the wax combining with the chlorine to form hydrochloric acid, and the carbon being set free. Chlorine, in common with several other elementary bodies, has the property of replacing hy-drogen in its organic compounds. It is in this manner that chlorine bleaches textile fabrics. The brownness of the fabric is due to some brown organic substance, which, when submitted to the action of chlorine, parts with its hydrogen and assumes a colourless form, containing chlorine. This fact is proved on a large scale by the action of chlorine on indigo. Another property of chlorine is that of destroying noxious vapours and miasmata. For the same reason, it is used as a disinfectant, the action being the same as that mentioned above. For laboratory use, chlorine is best made as follows :- Oil of vitriol and water, of each seven parts. follows:—Oil of viriol and water, of each seven parts, Allow the mixture to cool, and add four parts of chloride of sodium, mixed alternately with three parts of peroxide of manganese. The gas comes off slowly at irrst until the application of a gentle heat, when it immediately rushes forth in large quantities. The manufacture of chlorine for bleaching purposes is described under Bleaching-Powden. Chlorine is possessed of powerful affinities, and unites with all the metalloids and metals. With oxygen it forms five compounds. powerful alimities, and unites with an ene inclamate and metals. With oxygen it forms five compounds,—hypochlorous acid, ClO; chlorous acid, ClO;; peroxide of chlorine, or hypochloric acid, ClO;; chloric acid, ClO; perchloric acid, ClO;; all of which are described under their respective heads. With hydrogen it forms hydrochloric acid, and with nitrogen a fearfully explained perchloride of nitrogen. With expressions are considered to the constant of the const plosive substance,—perchloride of nitrogen. With carbon it forms several chiorides. (See Carbon.) In many of its properties, it bears a very strong analogy to its congeners bromine and iodine. The relation subsisting between the atomic weights of these three bodies is very peculiar, the equivalent of bromine being halfway between iodine and chlorine:—

2)162.5

80 being the equivalent of bromine. The same relation is carried out in the properties of these bodies, bromine standing halfway between the other two in bromino standing hailwayweetween the other two in be collected by displacement, as it acts both on messpecific gravity, colour, affinity, solubility, and consistency. Chloride of iodine, too, possesses many proporties in common with bromine. Whether bromine wildow, wood), in Bot., a gen. of tropical trees belonging

### Chloroxylon

will ever be discovered to be a chloride of foding a not, is a question to be answered by the chemistry of

CHLORINE-WATER.—Water at 60° absorbs two vol-umes of chlorine. When freshly made, this solution possesses all the properties of the gas. It gradually becomes decomposed, liberating oxygen and forming

hydrochloric acid.

hydrochloric acid.

Chichororam, klor-o-form (prefix chloro, and formyl!,—C,HCl,.—This interesting compound is preduced by a variety of reactions. The most usual way
of preparing it is by acting upon dilute alcohol with
chloride of lime. Six parts of chloride of lime are
mixed with twenty-four parts of water, and one part
of alcohol is added to the mixture; the whole is transferred to a capacious still, and the heat is quickly
raised until it reaches 180°. The products, which consist of chloroform and water, collect in two layers, the
lower of which is chloroform. It is senarated from lower of which is chloroform. It is separated from the water by means of a pipette, agitated with sulphuric acid, and once more distilled. Chloroform is a colour-less, volatile, mobile, highly refracting liquid, of specific gravity 1497, and boiling at 1429 Fahr. It has an ethercal odour, and a sweetish penetrating taste, it is readily soluble in ether and alcohol, but sparingly so in water. Concentrated sulphuric acid has but little parties out it and active the contraction out the order teacher the sulphuric acid has but little action on it, and potassium does not decompose it. It yields, however, to the action of light, and should be tested for alcohol and other products of decomposition before it is used for an exthetic purpose. Pure chip-roform, when dropped into water, should fall to the bottom without becoming milky. Alcohol is detected in it by its turning green on the addition of bichromate of potash and sulphuric acid. It should remain colourless when oil of vitriol is agitated with it, and the liquid itself should be perfectly colourless, and free from any chlorous odour. The vapour of chloroform has the remarkable property of rendering a person action on it, and potassium does not decompose it. from any chlorous odour. The vapour of chloroform has the remarkable property of rendering a person breathing it temporarily insensible to pain. To Professor Simpson, of Edinburgh, is due the credit of introducing chloroform as an anesthetic. (See Ann-STRETICS.) Chloroform is an excellent solvent for sal-STRETICS.) Chorotorin is an excellent solvent to such that phosphorus, and iodine. It also readily dissolves latty and resinous bodies. It is a perfect solvent of caoutchouc, which is left unaltered on evaporation. Chemists are at variance as to the real composition of chloroform, some regarding it as a derivative of methyl, others looking on it as a terchloride of formyl. There are other chlorides derived from the same source, having the formulæ C<sub>2</sub>HCl<sub>2</sub> and C<sub>3</sub>HCl<sub>3</sub> bet source, naving the formulae C<sub>2</sub>MCl<sub>2</sub> and C<sub>2</sub>MCl<sub>2</sub> and they have not yet been proporty studied. Iodine and bromine form similar substances,—iodoform and bromoform, having the formulae C<sub>2</sub>Ml<sub>2</sub> and C<sub>2</sub>MBr<sub>3</sub>. Chlorosts, kloro-isis (Gr. chloros, green), in Med., is the name of a disease to which young females are

subject, and which is characterized by a peculiar sallow or greenish-yellow huo of the countenance, and hence known as the green sickness. It is usually attended with great debility, palpitations of the heart, difficulty of breathing, pains in the back and loins, and other distressing symptoms. The principal means to be employed in the cure of this disease are gentle exercise in the open air, with nutritious and rather stimulating diet, tonics, sea-bathing, and agreeable

society.

Chlorosponæ. (See Algæ.) Chlorous Acid, klor'-ous (ChO<sub>a</sub>), one of the oxides of chlorine. It is a dark greenish-yellow gas, possess ing a purgent odour and bleaching properties. If heated to 135° Fahr, it explodes, being resolved into chlorine and oxygen; it also explodes when placed in contact with combustible substances. By intense cold and pressure it may be reduced to the form of a red liquid. Water dissolves about six times its volume of liquid. Water dissolves about six times its volume of the gas, the solution varying in colour from green to yellow, according to the degree of saturation. Chlorous acid has powerful bleaching properties, and combines with bases to form chlorites, many of which are crystallizable. It is expelled from its combinations by carbonic acid. It is prepared by heating nitric acid, chlorate of potash, and arsenious acid. The gas must be collected by displacement, as it acts both on measure and water.

to the nat. ord. Cedrelaces, or Mahogany fam. to the nat. ord. Convences, or managiny iam. All the species have dotted leaves, which yield by distillation an essential oil. C. Swistenia furnishes Indian satin-wood, which is sometimes imported into this country for the use of cabinetmakers. Boyle states that this tree is one of the plants that yield the wood-old finding. (See December 1982)

cui of India. (See DIPTERCOLARDS.)
CHOCOLATE. (See THEOBROMA.)
CHOIN, quire (Gr. chores, Lat. chorus, Fr. chour,
Bax. and Ger. chor), is that part of a church or cathedral where the singers or choristers chant or sing divine service. It is also applied to those whose special duty it is to perform the service to music. Every chair is divided into two parts, stationed on each side of the choir, in order to sing alternately the verses of the palms and hymms, one side answering to the other. The choral service in the English churches had been much neglected, but a great improvement in this respect has taken place within the last forty or fifty Years.

CROKE-DAMP, tshoke'-dümp (Ang.-Sax.), a name given by miners to carbonic acid, as distinguished from the-damp, which is carburetted hydrogen.

CHOLERA, kol'-e-ra (Gr. chole, bile, and rheo, I flow) in Med., is the name given to two or three different forms of disease, each of which is characterized by vomiting and purging, with great pain and debility. The mildest form of this disease is known as bilious or British cholera, and usually prevails to a greater or less extent in this country every summer or autumn. It apparently proceeds from some disordered condition of the bile, which is either in excess or too acrid, and ie bile, which is either in excess or too scrid, and seems to be produced by cold, suppressed perspira-tion, unripe or acid fruits, &c. It generally commences with griping pains of the bowels, followed by vomiting and purging, together with heat, thirst, a hurried respiration, and a frequent but weak and fluttering pulse. In favourable cases these symptoms subside in a few days, leaving the patient in a very weak and exbausted condition; but in severe cases great depression bassted condition; but in severe cases great depression of strength ensues, attended with great anxiety and lowness of spirits, violent spasms, cold clammy sweats, a hurried and short respiration, hiccup, a low and irregular pulse, and the patient sinks rapidly, being sometimes carried off in twenty-four hours. In the earlier and milder form of this disease, when the strength is not much exhausted, tepid demulcent liquids are to be frequently administered, so as to lessen the irritation and facilitate the discharge of the Where the symptoms are severe and the patient rapidly sinking, opium is to be administered freely, rapidly sinking, opium is to be administered freely, but in small quantities, and effervescent saline draughts given to check the sickness, and enable the atomach to bear the frequent doses of opium. When the urgent symptoms are relieved, the strength is to be restored by gentle tonics and a light and nutritious diet. The neverer form of this disease is sometimes called spasmodic cholers, from being usually attended with violent and the first property of the strength of the epasms. The Asiatic, malignant, or pestilential choiers, is a much more violent form of disease, and first became known in this country in the autumn of 1831. commonly comes on without any warning, and the patient is frequently a corpse in a few hours. The attack usually begins with sickness and purging; the discharge in this case not being bilious, but a thin colonriess fluid like rice-water, accompanied with great prostration of strength and cold clanmy sweats. In a short time dreadful cramps assail the extremities, and afterwards the abdomen and other parts of the body; the body becomes bent, the limbs twisted, the secuntenance cadaverous, the pulse almost impercepti-ble, the eyes sunken and surrounded by a dark circle, the patient sinks into a state of spathy, and, unless a favourable change speedily takes place, he soon ex-pires. When reaction takes place, the pulse gradually returns, the natural warmth of the body is restored, and the spasms and difficulty of breathing give way. and ane spasms and dimenty of breating give way. Brequently, however, the reaction is accompanied by fever, closely resembling typhus, and which often terminates fatally, in from four to eight days. As regards the treatment of this disease, the only advice that can be given here is, to seek the aid of a medical way without delay.

carrageon, or Irish moss, which is used medicinally for its nutritive, emollient, and demulcent properties, being administered in the form of a decoction or jelly. It is also used for making bandoline (which see), and as a substitute for size. C. mamillosses, which has similar properties, is always found in the carrageen moss of the shops.

CHORAL SERVICE, kord-al, of the English church is when those parts of the service ordered in the rubrice are sung by a full complement of clergymen and che-

risters in a cathedral church.

CHORD, kord (Lat. chorda), in Geom., is a right line drawn from one part of an arc of a circle to another. The term is also applied to the string of a musical instrument.

CHORD, in Mus., the harmonious combination of three or more musical sounds. Before the introduction of simultaneous sounds, it was solely applicable to a distended sonorous string; but after the discovery of counterpoint, and the formation and establishment of various combinations, a general term became necessary to express those combinations, and that which before applied only to a single string was now borrowed, and its sense extended to a union of the sounds of several strings, pipes, or voices. In practical music there are several kinds of chords; i.e. the fundamental chord, consisting of the third, fifth, and eighth of the fundamental bass, or their inversions;—the accidental chord, which may result from either of two causes, viz., anticipation or retardation; by anticipation when their construction assumes some note or notes of a succeeding chord (a chord not yet struck); by retardation when one or more notes are, by suspension, carried in to the composition of the succeeding chord;—the anomalous or equivocal chord, in which some interval or intervals are greater or lesser than those of the fundamental chord ;- and the transient chord, in which some intermediate notes are introduced to smoothen the transition from one chord to another, which do not form any component parts of the fundamental, and cannot be justly called either anticipations or suspensions.

HOREA, kor-e'-a (Gr. choreia, a dancing or jumping), in Med., is the name of a disease otherwise known as St. Vitus's Dance, and characterized by convulsive motions of the limbs, as of a person dancing. The muscles of voluntary motion are no longer under the complete control of the will, and the power of walking or of using the arms or hands is impaired. It is comor of using the arms or hands is influence. It is common to both sexes; but rarely attacks before the age of eight or after that of sixteen years. Those of a weakly constitution, or whose health has been impaired by confinement or improper nourishment, are chiefly subject to it. The great cause of it is a disordered state of the digestive organs, producing a certain degree of mental weakness. The patient is at first restgree of mental weakness. The patient is at first rest-less, irritable, fretful, and gloomy. After a time there come on irregular and involuntary twitchings of the nuscles; he cannot walk steadily, or drags one leg after him; the arms become affected, and the muscles of the face, head, and trunk may become at different times and in different degrees, affected by it. This disease usually disappears under judicious treatment, or as the patient grows up; but occasionally it terminates in epilepsy, paralysis, or idiotcy. The proper mode of treatment is to restore the tone of the system by tonics, a nourishing diet, and frequent exercise in the open air, with occasional purgatives, if necessary.

Chorus, kor'-us (Lat.), among the ancients, denoted a number of singers and dancers employed on festive occasions, and also in the performance of plays. During the most flourishing period of Attic tragedy, the chorus consisted of a group of male and female personages, who remained on the stage as bystanders or spectators, and, during the intervals of the acting, chanted songs relating to the subject of the play. They sometimes even took part in the performance, by advice, comfort, consolation, or dissussion. In early times it consisted of terminates fatally, in from four to eight days. As a great number of persons, sometimes as many as fifty, but it was afterwards limited to fifteen. The leader that can be given here is, to seek the aid of a medical man without delay.

Chondry, kon'-drue, in Bot., t' gen. of Alga. The most important species is C. crispus, commonly called chorus was divided into two parts, which sang afternately. With the decline of ancient tragedy, the most important species is C. crispus, commonly called

#### Chorus

attempts have been made to restore the ancient chorus;

attempts have been made to restore the sucient chorus; as in Schiller's "Bride of Messins."

Chorus, in Mus., alindes, in its general sense, either to a composition of two, three, four, or more parts, cach of which is intended to be sung by a plurality of voices; or to the performers who sing those parts, and form what is called a chorus, or choral part of a band.

Chors, shows (Fr.), signifies a thing; and a chose in action is a thing of which a man has not the possession or extract any owners but he a right to demand the

or actual enjoyment, but has a right to demand the same by action; for property in things personal is of two kinds, —either in possession, where a man has not only the right to enjoy, but also the actual enjoyment of the thing; or else it is in action, where a man has only a bare right, without any occupation or enjoyment, the possession whereof, however, may be recovered by a suit in equity or action at law; from whence the thing so recoverable is called a thing or chose in action; and although a debt or right of action may be assigned, the assignee can only recover in the name of the assignor, except in cases of bankruptcy, where the law has given the power to the assignee to deal with the debt or right in his own name as assignee, it

being vested in him by operation of law.

Chouans, shoo an', was the name given to a party of royalist insurgents that appeared on the right bank of the Loire during the first French revolution. At first they were composed chicily of smugglers and other lawless persons; but they were speedily joined by peasants, priests, noblemen, and others. They are said to have taken their name from one Jean Cottereau or Chouau, a leader of one of their bands, and who fell in an engagement on the 2nd of February, 1794. As early as 1792, the marquis de la Roarie attempted to bring them to open insurrection; but, in consequence of his arrest, the attempt fell to the ground. In the following year Jean Cottereau succeeded in this attempt, and, for a time, the Chouannerie, as it was called threat-ened to imperil the security of France, and the guerilla warfare which followed gave employment to as many as 60,000 regular troops. At length, partly by force and partly by negotiation, the movement was put down; and though Chousanerie has, on more than one occasion since, attempted to make its appearance on the banks of the Loire (as in 1799 and in 1814-15), it has never again become formidable.

Chough, takuf (Sax. eeogh), (Fregilus graculus), a British bird, much resembling in size and habits the jackdaw; its colour, however, is in parts different. It is of a jet black over its upper parts, while the head and neck feathers are tinted with purple. The beak is bright vermilion, bent from the base, and very strong. The legs and feet are of the same colour as the beak, and powerfully formed. Its length, when full grown, is about fifteen inches. Like the jackdaw, the chough is easily tamed, and just as mischierous and entertaining when its domestication has been

accomplished.

CHRESTOMATHY, kres-tom'-d-the (Gr. chrestos, useful; manthano, I learn), is a name sometimes applied in literature to a collection of useful pieces out of the best authors. The analogous term anthology is usually limited to selections from the poets.

CHRIST, CHREROF. (See TRULLERS.) CHRIST-CHURCH COLLEGE, ONFORD, krist tshurtsh, owes its first foundation to Cardinal Wolsey, who, in 1525, obtained from Clement VII. a bull for the suppression of twenty-two monasteries, the aggregate revenues of which were estimated at nearly £2,000, in order to found and endow a college at Oxford, on the site of the priory of St. Frideswide. It was to have consisted of a dean, sub-dean, 100 canons, 10 public readers, 13 chaplains, an organist, 12 clerks, and 13 choristors, and was to have been culled the "Collego of Secular Priests;" but afterwards, the name was changed to "Cardinal's College." Before its comchanged to "Cardinal's College." Before its com-pletion, the cardinal had fallen into disgrace; and in 1532 the society was refounded by the king, under the title of "Henry VIII.'s College." In 1545 this was again suppressed; and in the year following it was re-established under the name of the "Cathedral Church of Christ in Oxford," for the maintenance of a dean, of Christ in Oxford," for the maintenance of a dean, it stands, nevertheless, in necessary connection with 8 canons, 8 chaplains, a schoolmaster, an organist, the essence of these powers and with their mede of 8 clerks, and 8 choristers, together with 100 students. development. Otherwise, indeed, it would not be By ordinance of the commissioners, under 17 & 18 fitted to raise them to higher perfection, and, in short,

## Christianity

Vict. c. 81, the number of canons is reduced to 6, a students to 80; of which 28 are senior students (with permanent tenure) and 52 junior students, of whom 21 are to be elected from Westminster school, and hold their places for seven years; the remaining 21 student-ships being open to all candidates who have not are ceeded their eighth term from matriculation, and are tenable for five years. Every third junior studentship is to be given for proficiency in mathematics and for proficiency in physical sciences alternately.—Ref. Oxford University Calendar, 1871.

CHRIST-CHOSS Row, kriste-kros-ro', was the name given to the letters of the alphabet arranged in the form of a cross, and used in the instruction of children. It is referred to in Shakepeare: "And from

the cross-row plucks the letter g.

CHRISTIAN KNOWLEDGE, SOCIETY FOR THE Pro-MOTION OF, an incorporated society for the education and religious instruction of the poor, supported by the members of the Church of England, and the oldest society of the kind in the kingdom. It was founded society of the kind in the kingdom. It was founded by the Rev. Dr. Thomas Bray in 1698, and was in-corporated in 1701, its objects being, "(1) to promote and encourage the erecting of charity schools in all parts of England and Wales; (2) to disperse, both at home and abroad, bibles and tracts of religion; and, in general, to advance the honour of God and the good of mankind by promoting Christian knowledge, both at home and in other parts of the world, by the heat at home and in other parts of the world, by the best methods that should offer." These objects the society ever has, and still continues to keep in view. Numeever has, and still continues to keep in view. Numerous charity-schools have been established by it in all parts of the country large sums have been expended in behalf of missionary enterprises abroad; and bible and tract distribution are largely carried on. The accept annually expends about £100,000 in furtherance of these objects.

CHESTERIA NAME (See NAME)

CHRISTIAN NAME. (See NAMES.) CHRISTIANITY krist-c-dn'-e-te (from Christ, Gr. Christos, the Anointed One), is that religion which was instituted by Jesus Christ, and whose doctrines are con-tained in the books of the Old and New Testaments. When the filness of the time was come,—when the three great historical nations had each in its own peculiar way co-operated in preparing the soil on which Christianity was to be planted,—the Jews on the side of the religious element; the Greeks on the side of science and art; the Romans, as masters of the world, on the side of the political element;—then it was that through Him, and by the power of the Spirit that proceeded from Him—by the might of Christianity—all the threads of human development which had hitherto been kept apart were to be brought together and interwoven in one web.
Whilst, on the one hand, the seed of divine truth out whilst, on the one hand, the seed of divine that does of which Christianity sprang was communicated to reason by divine revelation; so, on the other hand, reason, unfolding itself from beneath, had to learn by reason, unfolding itself from beneath, had to learn by experience, especially among the Greeks, how far, singly, and by its own power, it could advance in the knowledge of divine things. The preparations, made by the previous development of the history of nations had been leading precisely to this point, and were destined to proceed just so far in order to admit of Christianity, the goal and centre-point of all. "We look upon Christianity," says Neander, "not as a power which has sprung up out of the hidden depths of man's nature, but as one which descended from above, when heaven opened itself anew to man's long alignated race: a power which, as both in its long alienated race; a power which, as both in its origin and its essence it is exalted above all that human nature can create of its own resources, was designed to impart to that nature a new life, and to change it in its immost principles. The prime source of this power its inmost principles. The prime source of this power is He whose life exhibits to us the manifestation of it is it o whose He exhibits to us the manuestation of hedesia of Nazareth, the Redoemer of mankind, when estranged from God by sin. In the devotion of faith in Him, and the appropriation of the truth which He revealed, consists the essence of Christianity."

"Rut, although Christianity cannot be understood except as something which, being above nature and reason, is communicated to them from a higher source,

would be unable to exercise any influence upon them." This connection consists therein that whatever has by their Creator been implanted in the essence of heman nature and reason, whatever has its ground in their idea and their destination, can only attain to its full realization by means of that higher principle, such as we see it actually realized in Him who is its source, and in whom is expressed the original type and model after which humanity has to strive. And accordingly we discover abundant evidence of this connection when we observe human nature and reason, and see how by wirtue of this, their original capacity, they do, in their historical development, actually strive after this higher principle, which needs to be communicated to them in are the control of th to assimilate it to its own nature, and to imbue it with its own spirit, that on a superficial view Christianity itself appears to be only a result produced by the joint action of the several spiritual elements it had drawn together. And for the same reason it may also be blended for a while with the impure elements which it attracts by its influence, and so in its temporary manifestation assume a shape which wholly resembles them; but at last by its own intrinsic power it begins a process of purification, from which it issues refined and emobled even in its outward form. In the history of Christianity we have the growth of that mighty tree which, springing up from the little grain of mustardseed, is destined to overshadow the earth, and under the branches of which all nations are to find a safe lodging. We "survey a process of development in which we ourselves are still involved,—a process which, noving steadily onwards, not always in a straight line, but through various windings, is yet in the end furthered by whatever attempts to arrest its progress, a process which, having its issue in eternity, constantly follows the same laws; so that in the past, as it unfolds itself to our view, we may see the gorm of the future which is yet to meet us." The history of Christianity materally divides itself into two branches,—the external and internal, a cording as the events of which it is made up have happened to the Church from without, or have been transacted within its own body. To the ernal branch belongs, first of all, the history of that sigious faith which forms its bond of union both in scientific development and life in the members; ext, the character of the public religious exercises; and thirdly, the form of government. To the external stations of the Church belong, first, its diffusion, and, second, its relation to other associations, particularly the state. In the treatment of the history of Chrismaity, the old system of division into centuries has been rightly abandoned, and a division into epochs lopted instead, though considerable difference of ion exists as to determining the different epochs. Bender divides the period from the introduction of Christianity to the Reformation into six epochs, empirising, (1) the first three centuries, or down to a.s. 312; (2) from the end of the Diocletian persecution to the time of Gregory the Great, bishep of the Christian of Gregory that time of Gregory Reme (312—590); (3) from the time of Gregory the Great, bishep of Reme (312—590); (3) from the time of Gregory the Great to the death of the emperor Chailemagne (390—814); (4) from the death of Charlemagne to Peope Gregory VIII. (314—1973); (5) from Gregory VIII. (314—1973); (5) from Gregory VIII. (1073—1294); (6) from Bosiface VIII. to the beginning of the Reformation: The history of each epoch is divided into four meritions:—(1) the relation of the Christian Church to the world, its extension and limitation; (2) the Church constitution, Church discipline and schisms; (3) Christian life and Christian worship; (4) Christianity appresented and developed as a system of doctrines. Dr. Gionelar divides ecclesiantical history into four periods:—(3) from the introduction of Christianity to the time (1) from the introduction of Christianity to the time Constantine (i.e. till 324), when the acknowledgment of the Church in the Roman empire was secured,—the first development of the Church under external oppression; (2) from the time of Constantine to the pression; (2) from the time of Constantine to the pression; (2) from the time of Constantine to the pression; (2) from the time of Constantine to the pression; (2) from the time of Constantine to the pression of the controversies concerning image-worship (324-728),—the development of Christianity as the pression of the state; (3) from the beginning of the controversies to the single of the fields by night in the middle of the limit seed on the controversies to the account for the choice of the 25th of De-

—the development of the Papacy prevailing over the state; and (4) since the time of the Reformation, the development of Protestantism. The evidences in favour of the truth of Christianity are divided into external and internal. The external evidences are those that tend to prove the authenticity and divine authority of the Holy Scriptures, and have been divided into direct and collateral. The direct evidences are such as exise from the nature, consistency, and probability of the facts, and from the simplicity, uniformity, competency, and fidelity of the testimonies by which they are supported. The collateral evidences are either the same occurrences, supported by heathen testimonies, or others which concur with and corroborate the history of Christianity. Its internal evidences arise either from its exact conformity with the character of God, from its aptitude to the frame and circumstances of man, or from those supernatural convictions and assistances which are impressed on the mind by the im-Pope Pius IV. and the Catechism of the Council of Trent; (2) the Eastern, or Orthodox Greek Church, the creed of which is defined in the symbol entitled the creed of which is defined in the symbol entitled "The Orthodox Confession of the Catholic and Apostolic Greek Church' (1642); (3) the unti-Byzantine Eastern churches of Armenia, Syria, Egypt, and Chalden; (4) the Protestant Lutheran clurches holding the Confession of Augsburg (1539); (5) the Protestant churches holding the Galic, Helvetic, and Belgie Confessions; (6) the Protestant Episcopal churches holding the Thirty-nine Articles of the Anglican church; and (7) the Protestant churches adhering to the Westminster and Savoy Confessions."—
[Conder.] The total number of professing Christians (Conder.) The total number of professing Christiana is estimated at about 300,000,000, of which, probably, nearly one-half are Roman Catholies, about 65,000,000 belonging to the various sects of Protestants, and probably a like number to the Greek church. The principal points in the history and doctrines of Christianity will be found noticed under their proper heads in different parts of this work.

Christians, krist wins, are those who profess Christianity, or the religion of Jesus Christ. (See Christnanty.) The disciples, we are told, were called Christians first at Antioch.

CHRISTIANS OF ST. THOMAS is a name applied to a people residing on the Malabar coast, in the south of India, and who profess the Christian religion. The Portuguese navigators, by whom they were first visited, represent them as professing to have received Christianity from the apostle Thomas, who is by some believed to have carried the Gospel into India. Others regard them as the descendants of a colony of Nestorians; but the most probable conjecture is that they are an offshoot of the ancient Christian churches in Persia. They have the episcopal form of government. and are said to acknowledge the patriarch of Antioch; and are said to acknowledge the patriarco of Andoon; their churches contain no symbols or pictures, except the cross; their priests are allowed to marry, and they celebrate the Agapm.

CHRISTIANS. OF THE CHRISTIAN CONNECTION, a sect of Christians which arose in America in the beginning of the present century. They profess to re-

ject all creeds and all sectarian distinctions, and to receive the Scriptures as the only rule of faith and practice, each member being at liberty to determine for himself as to what is enjoined. They practise baptism by immersion and open communion, and the great majority of their members are professed Unitarians. Their members are estimated at about 300,000, and their ministers at 600.

Christman, krist mile (Christ, and Ang. Sax. mas, a holiday or feast), a Caristian festival observed in memory of the nativity of Christ, on the 25th of December. The exact day of the nativity of Christ has long formed matter of dispute; but it is generally agreed that it could not have been on the

cember,—the winter solstice, by showing, that not only the feast of the Nativity, but most of the others, were originally fixed at cardinal points of the year, and that the first Christian calendars having been so arranged the first Christian calendars having been so arranged by mathomaticians at pleasure, were afterwards adopted by the Christians as they found them in the calendar, the main object being to have a fixed time of com-memoration appointed. Be this as it may, the 25th of December has been the day fixed upon for the com-memoration of the nativity from the carliest ages of the Church. The festivities that used formerly to characterize this period have now, in a great measure, passed away. According to Polydore Virgil, the English were remarkable for the festivities with which they distinguished Christmas; and these are given at considerable length in Brand's "Popular Antiquities." On the night of Christmas-eve, it was usual to light up candles of uncommon size, called Christmas candles, and to lay a log of wood upon the fire, called a Yule clog or Christmas block, to illuminate the fire, and as a second state of the control of the cont it were, to turn night into day. At court and in dis-tinguished families, an officer, under various titles, was appointed to preside over the revels. Stowe says, "that in the feast of Christmas there was in the king's house, wherever he lodged, a Lord of Misrale or Master of merry Disports; and the like had ye in the house of every nobleman of honour or good worship, were he spiritual or temporal." The mayor of London and he spiritual or temporal." The mayor of London and cach of the sheriffs had their several Lords of Misrule. The Puritans in England were very much opposed to these ceremonies; and in Scotland, the Abbot of Unreason, as he was there called, was suppressed by act of parliament in 1555. Yule seems to have been originally a pagan festival, observed in ancient times among the Romans, Saxons, and Goths, in commemoration of the temperature of the suppression of the second services. ration of the turning of the sun and lengthening of the day, and was afterwards kept up by the Christians. In a tract, entitled the "Vindication of the Solemnity of the Nativity of Christ," by Thomas Warmstry (1638), it is said, "If it doth appeare that the time of this festival doth comply with the time of the heathens' saturnalia, this leaves no charge of impiety upon it; for since things are best cured by their contraries, it was both wisdome and piety in the ancient Christians (whose work it was to convert the heathens from such as well as other superstitions and miscarriages) to vindicate such times from the service of the Devill by appoynting them to the more solemne and especial service of God." The custom of decking churches and houses at Christmas with laurel, box, holly, or ivy, appears also to have been copied by the Christians from their pagan ancestors.

CHRISTMAS-BOX, is a small sum of money given to servants and others on the day after Christmas, which is hence called Boxing-day. The practice was, undoubtedly, founded on the pagan custom of new-year's gitts; and, until recently, it had spread to such an extent as to have become almost a national griev-Tradesmen sent their journeymen and apprentices to levy contributions on their customers, and they, on the other hand, bestowed boxes on the servants of their customers. To the tradesman it was a pretence for lengthening out his bill; to the master and mistress for lowering the wages of their servants. In 1836 the secretary of state for foreign affairs issued a circular to the different embassies, requesting a dis-continuance of the customary Christmas-boxes to the messengers of the foreign department and others; and since that time the practice has very much decreased.

CHRISTMAS CAROLS. (See CAROLS.)
CHRISTOLOGY, kris-tol'-o-je (Gr. Christos, Christ, and logos, discourse), is the doctrine of the person of Corner, a term applied to such treatises as those of Owen, Neander, Hengstenberg, and Dorner, which profess to expound what is taught in Scripture respect-ing the person of Christ.

CHUISTOPHOEI, kris-tof-o-ri (Gr., Christ-bearers), a name sometimes given to Christians in the early Church to denote the communion that exists between Christ and the Church.

Christ and the Church.

CHRIST'S COLLEGE, CAMDRIDGE, was founded in 1505, by Lady Margaret, councess of Richmond and Derby, nother of Henry VII., for a master, twelve chromine used in commerce. The mineral, which efellows, and forty-seven scholars. Edward VI. added sixts of protoxide diron and sequinoide of chromine and sequinoide of chromate is reduced to powder, fused in a reverberatory fuses one fellowship and three scholarships, and several

others were added by subsequent benefactors recent arrangements, the scholarships have bee solidated and greatly improved in value; and sent the college consists of a master, fifteen fol and twenty-nine scholars. The fellowships and sola ships are now open to all the queen's subjects, with

restriction or appropriation.

CHRIST'S HOSPITAL, LONDON, was established up the site of the Grey Friars' monastery, in terms of charter granted by Edward VI., 26th June, 1553, as hospital for poor fatherless children and orpham is commonly called the Bine-coat School. dress worn by the boys, which consists of chine of or gown, a yellow petticost and stockings, a r black bonnet or cap, a red leather girdle round the waist, and a clergyman's band round the neck. 1672 the mathematical school was founded by Chaster II. for forty boys, who are distinguished by a badge on the right shoulder, and called "King's boys." Subsequently another foundation was added by a Mr. Stone, the boys on which wear a badge on the left shoulder, and, from their number, are called "the Twelves;" and afterwards "the Twos" were added on another foundation. The governing body is composed of the mayor, aldermen, and twelve common counsilmen of the city of London, and contributors of semantic for the city of London, and contributors of semantic cach to the hospital funds amountine in all to uswards. 1672 the mathematical school was founded by Ch each to the hospital funds, amounting in all to up of 500. Boys are admitted between the ages of se "King's boys" or Grecians, i.e. to the highest ele-formerly six, but now eight Grecians, are seast, various scholarships, to Oxford and Cambridge. I right of presentation is vested in the governors. lord mayor has two presentations aunually; each the aldermen one; and the other governors one in eve The foundation-stone of the New Hall three years. three years. The foundation such that the tree was laid in 1825, and it was publicly opened in 1825; the architect being the late Mr. James Shaw. A branch school was established at Hertford in 1883 for the education of younger children, boys as well girls; the former being maintained and educated until they are capable of being received into the London hospital. The average number constantly maintained and educated in both establishments is about 1,209 (800 in London and 400 in Hertford), and the amount revenue and expenditure are each generally as £56,000. The New Hall of the hospital fronting No. gate Street is one of the chief ornaments of the City Among the eminent men who have been educate here are Camden the historian, Bishop Stillingfleet Richardson the novelist, S. T. Coleridge, Charles Lumb, and Leigh Hunt.

CHROMATES, kro'-maits (from chromium).—Chromacid combines with bases to form three classes of salts,

basic, neutral, and acid. Most of the chromates are highly coloured. The most important are described under Chromate Are.

CHROMATICS, kro-mät'-iks (Gr. chroma, colour; terminal-ikos), a term applied to that part of the science of Optics which explains the properties appertaining to the colours of light. White light consists of different coloured rays and had with different colours of the science and the different coloured ways and had with different colours of the science of the s ferent-coloured rays, each enducd with different degrees of refrangibility; and the different colours of bodies depend upon the power they have of ab-sorbing or reflecting certain coloured rays. A sur-face that appears blue reflects that colour more than the others, which are absorbed; a white surface reflects all and absorbs none; while a black surface absorbs all and reflects none. By analyzing a ray of adsorbs an and reflects hole. By analyzing a lay-solar light with a prism, Sir Isaac Newton first de-nonstrated the unequal refrangibility of the various coloured portions. He also concluded, from his experiments, that white light consists of seven colours red, orange, yellow, green, blue, indigo, and violetz these he called the primary colours. According to Sir David Brewster, there are only three primary colours,—blue, yellow, and red. A theory has recently been propounded, that colours are the results of the mixture of white light with shade. (See LIGHT, Orange Spream) TICS, SPECTRUM.

CHROME IRON-ORE, OF CHROMITE, krome, an importa ore of chromine, from which are obtained the salts of chromine used in commerce. The mineral, which con-sists of protoxide diron and sesquioxide of chromine. with balf its weight of nitre, and stirred continually. In this manner the chromium is converted into chromate of potash. The mass is dissolved out with hot water, and the silica and alumina are precipitated by

water, and the since and aluming are precipitated by some strong soid, which at the same time converts the neutral chromate into the acid bichromate.

CHROME OCHER, a mineral consisting chiefly of oxide of chromium, found in fine yellowish-green masses, which are generally so mixed up with the rock in which it is found, that it is impossible to separate the strong strong

rate them except by chemical means.

CAROME, ORANGE.—Dichromate of lead, which is of a splendid orange-colour, is obtained by adding to a solution of nitrate of lead a solution of chromate of potash, to which an equivalent of hydrate of potash has been added. It is obtained of a still more brilliant colour by fusing together five parts of nitre and one part of chromate of lead. Chromate of potash and dishromate of lead are formed, and the former salt is

removed by washing.
ORROWS YELLOW, a valuable pigment, made by precipitating a salt of lead with bichromate of potash.
It is much used on account of its brilliant yellow

Chromic Acid, kro'-mik (CrO<sub>3</sub>).—This acid occurs in nature in combination with lead as chrome yellow, and with iron as chrome iron-ore. It is prepared by adding one measure of a warm saturated solution of bichromate of potash to one and a half of concentrated sulphuric acid. The acid is added in small portions at a time, the solution being allowed to cool between each addition. Chromic acid crystallizes out, and bisulphate of potash remains in solution. The crystals of chromic acid must be removed with a platinum lanie, and set to drain in a funnel stopped with as-They must not be heated or brought into contact with organic substances. As soon as the greater part of the sulphuric acid has drained away, the crystals are dissolved again and recrystallized under needles, which are very deliquescent, and soluble in water. Although chromic acid is one of the most powerful oxidizing agents known, it is easily decom-posed by light and organic substances. When absolute sicohol is poured on crystals of chromic acid, the former is oxidized with sufficient energy to cause combustion, the chromic acid being reduced to sesquioxide of chromium. Sugar and other organic substances have the same power of decomposing chromic acid. Chromic acid bears great analogy to sulphuric acid Both these acids are isomorphous; they are monobasic, and they form an acid and a neutral salt.

The most useful of these compounds of chromic acid is the bichromate of potash, which forms fine red tubular crystals, which are anhydrous, and remain unchanged by exposure to the sir. Bichromate of potash dissolves in ten parts of cold water, the solution having a fine red colour and an soid reaction. The chromate is easily formed from the bichromate by neutralizing its solution with carbonate of potash, and crystallizing. Both the chromate and the bichromate are extensively used in dyeing and calico-printing. Bickromate of potash is employed in conjunction with sulphuric soid in the laboratory as an oxidizing agent, and in commerce in the same manner in bleaching sperm oil. The bichromate of ammonia is used in photography. Except the chromate of lead, which is described under CHROME YELLOW, the other chro-mates and bichromates are unimportant.

CHROMIUM, kro'-mi-um (Gr. chroma, colour),-symbel Cr. equivalent 26.27, spec. grav. 5.9,—a pretty rare element, first shown to be a metal by Vauquelin, in 1797. Its most important ore is the chrome iron stone, a compound of protoxide of iron and sesquioxide of chromium. It is also found as chromate of lead, from which mineral Vauquelin first obtained it in the metallic state. To effect its reduction, oxide of chromium is intimately mixed with powdered charcoal, and made into a paste with oil. It is then introduced into a crucible lined with charcoal, and carefully luted The whole is exposed to the action of a power-

passing the vapour of sodium over the aesquiexide heated to redness. By heating seequichloride of chro-mium with potassium, a grey metallic powder is formed, which consists of chromium in an allotropic condition. Chromium is a light-grey metal, very brittle, non-volatile, and non-magnetic. As might be inferred from the difficulty with which it is reduced, chromium, in the metallic state, has not yet received any useful application. Its oxide and many of the chromates have received useful applications in calico-printing and china-painting. The manufacture of biohromate of potash is very important, not less than 1,500 tons of chrome iron-stone being annually imported from the United States and Norway, to be converted into this useful salt.

CHROMIUM, CHLORIDES OF.—There are two principal chlorides of chromium,—the protochloride, CrCl, and the esquichloride, Cr<sub>2</sub>Cl<sub>3</sub>. The former is formed by passing a dry current of hydrogen over the sesquichloride heated to redness; hydrochloric scid is given off, and the protochloride remains in the form of a white powder, soluble in water, with which it forms a bluish-green solution that rapidly absorbs oxygen from the air.—Seeguichloride of chromium is formed in beautiful transparent plates of the colour of peachblossoms by passing a current of dry chlorine over a mixture of sesquioxide of chromium mixed with charcoal contained in a porcelain tube heated to redness. Being volatile, the sesquichloride condenses at the cool end of the tube in the beautiful form just described. Thus prepared, it is quite insoluble in water and acids. Solution of sesquichloride of chromium is prepared from the hydrated sesquioxide by dissolving it in hydrochloric acid. The solution, on evaporation, yields green crystals, containing two equivalents of hydrochloric acid and ten equivalents of water. It is a singular fact, that only two-thirds of the chlorine contained in the solution of this salt is precipitated by nitrate of silver. A violet chloride may be formed by precipitation from the violet sulphate by chloride of barium, from the solution of which the whole of the chlorine can be precipitated by nitrate of silver.
CHROMIUM, OXIDES OF.—Chromium forms several

compounds with oxygen, of which the most important are four:—Protoxide, CrO; sesquioxide, Cr<sub>0</sub>O; chromic acid, CrO<sub>3</sub>; perehromic acid, CrO<sub>3</sub>; perehromic acid, Cr<sub>0</sub>O;—Protoxide of chromium can only be obtained in the state of bydrate on adding caustic potash to a solution of the proto-chloride. It absorbs oxygen with great avidity, de-composing water and setting free the hydrogen, becoming converted into a hydrated intermediate oxide. The protoxide of chromium forms a double sulphate with sulphate of cotash, closely corresponding to the double sulphate of iron and potash in form and composition. The crystals are of a fine purple colour.—
Sesquioxade of chronium is obtained as a greyishgreen hydrate, by boiling with alcohol a solution of bichronaste of potash aciduated with sulphuric soid.

The alcohol spice held the oxygen of the hydrate acid. The alcohol seizes half the oxygen of the chromic soid, leaving the sesquioxide free to form a sulphate with the sulphuric acid. On the addition of ammonia, a bulky gelatinous greyish-green precipitate of hydrated sesquioxide is produced, which, when dry, contains ten equivalents of water. In the hydrated condition it is readily soluble in acids, forming salts which do not crystallize. These saits, like the oxide, exist under several conditions, each condition giving rise to dissimilar properties. As this subject is rather complicated, the reader is referred to the article isomensms, where the subject is fully treated. The anhydrous green oxide is not decomposed by heat; hence it is of great use in china- and enamel-painting. It is generally prepared for this purpose by exposing chromate of mercury to a red heat. The difficulty with which this oxide is decomposed by ordinary chemical re-agents has rendered it useful as a pigment for printing bankers' cheques and other important documents; but a great objection to its use is the fact of its being so hard that the pens used for writing upon drafts printed by it are speedily worn out. Oxide of chromium is the colouring matter of the emerald, pyrope, greenstone, and other minerals.—Chromic acid has already been considered, under that head.—Perchromic acid is formed by adding fall wind-furnace for several hours, and an impure minerals.—Chromic acid has already been considered, mixture of carbon and chromium is formed in the crucible. M. Fremy has lately succeeded in procuring an aqueous solution of peroxide of hydrogen to chromium in the form of cubical metallic masses, by

#### Chronic

is rapidly decomposed with evolution of oxygen. If, bowever, the solution is agitated with ether, the per-chromic soid is isolated without decomposition, and may be made to form pretty stable salts with ammonia and certain organic bases. Strong saids decompose these salts, setting free the blue perchromic said. Chronic, kron'-ik (Gr. chronos, time), a term applied in medicine to such diseases as are of long durations.

tion, as contradistinguished from acute,-those that

soon terminate either in recovery or death.

CHROWIGLE, kron-i-kl (Gr.), denotes a history in which the events are narrated in the order of time. It is nearly synonymous with annals, the only distinction between the two being, that chronicles are generally more full and connected. The term is now seldom used except in speaking of our old English histories; as Holinshed's Chronicle, Stow's Chronicle. It is sometimes taken as the name of a newspaper; as the Morning Chronicle.

CHEONICLES, the name given to two books of the Old Testament standing thirteenth and fourteenth in our English version. In the Hebrew they are called Books of Days, i.e. diaries; and in the Septuagint things omitted, or supplements, from their being in some measure supplementary to the books of Kings which precede them. The first nine chapters of the first book contain a great variety of genealogical tables, beginning with Adam, which must have been very valuable to the Jews after their return from the captivity. The more ancient are so obscure as to be hardly intelligible unless collated with the Pentateuch. The more modern are the most perspicuous; but even they are not complete. Nothing is to be found of the tribes of Dan or Zebulon; that of Benjamin is twice in-troduced; Judah is pretty copious; and the register of David's descendants runs down to the end of the 4th century before Christ (by some believed to be a later addition). The genealogies of the priests and Levites are given most in detail, and terminate with the destruction of Jerusalem.

CHRONOGRAM, krof-no-gram (Gr. chronos, and gramma, a letter), is applied to a verse or sentence, certain letters of which are in larger characters than the rest, to denote the date of the event to which it relates.

CHRONOGRAPH, kro'-no-graf (Gr. chronos, time; grapho, I write), is an instrument devised by Mr. Benson, the watchmaker, for taking the time of races. It is used on all occasions where it is essential to obtain the rate of speed with perfect accuracy. It consists of an ordinary quick-train movement of a lever watch, on a scale sufficiently large to carry the hands for an S-inch dial, and with the addition of a long seconds hand, which traverses the dial, instead of being, as usual, just above the figure VI. The peculiarity of the chronograph consists in this seconds hand and the mechanism connected with it. The hand itself is double, or formed of two distinct hands, one lying over the other. The lower one at its extreme end is furnished with a small cup, or reservoir, with a minute orifice at the bottom. The corresponding extremity of the upper hand is bent over so as to rest externity of the upper name is bent over so as to rest exactly over this puncture; and the reservoir having been illed with ink, of a thickness between ordinary writing-fluid and printers ink, the chronograph is ready for action. The operator, who holds tightly grasped in his hand a stout string connected with the mechanism peculiar to this instrument, keeps a steady look-out for the fall of the starter's flag. Simultaneously, therefore, with the start of the race, the string he holds is pulled by him, and, at the same moment, the upper hand dips down through the reservoir in the lower, and leaves a little dot or speck of ink upon the dial. This is repeated as the horses pass the winning-post, so that a lasting and indisputable record is afforded by the dots on the dial of the time-

record is afforded by the dots on the dial of the time—
exact to the tenth of a second—which is occupied in
running the race.—Ref. Mechanics' Magazine, vol. xv.
CHRONOLOGY, kro-nol'o-je (Gr. chronos, time, and
bogos, discourse), the science which treats of the
various divisions of time, distinguishing its several
parts,—such as centuries or ages, years, months,
weeks, days, hours, &c., and of the order of the succession of events.

CHRONEMETER, kro-nom's-ter (Gr. chronos, time; metron, a measure), literally any instrument for mea-

#### Church

suring time; the term is, however, generally applied to those time-measurers which are used for determin-ing the longitude at sea. The mechanism is essentially ing the longitude at sea. The mechanism is consuming the same as that of an ordinary watch, but the size is greater. In the construction of such chromometers special precautions are taken to allow for change of tamperature and other causes of derangement. (See HOROLOGY.)

CHRYSALIS. (See INSECT TRANSPORMATIONS.)
CHRYSANTERMUM. (See CORYMBIFER.)
CHRYSOBALANER, kriso-bai-lai-nee (Gr. chrusos, gold; balanos, a nut), in Bot, a sub-ord. of the net. ord. Rosacex. The plants belonging to this division are trees or shrubs, principally natives of the tropical parts of America and Africa. Many of them produce edible drupaceous fruits. The typical gen. Chrysobleanus includes two valuable fruit-trees. C. Legeo yields nus includes two valuable truit-trees. C. Leave yields the cocoa-plum of the West Indies; and in Brazil the roots, bark, and leaves are prescribed against disrrhea and other similar maladies. C. luteus yields a fruit

which is eaten in Sierra Leone.

Chuysornyllum, krissofil-lum (Gr. chruses, gold; phullon, a leaf), in Bot., a gen of tropical trees belonging to the nat. ord. Sapotaceæ. The species C. Cainito vields a delicious fruit known as the star-apple. C.
Buranheim furnishes the astringent bark called Monesia bark, which has been much employed in France and Germany. This bark contains an acrid principle called

monesine, which is analogous to suponine.

CHRYSOTYPE, kris'-so-tipe (Gr. chrusos, gold; tupos, impression), a process in photography invented by Sir John Herschel, in which pictures are produced by means of aumonio-citrate of iron and chloride of gold. (See Photography.)

CHUB, tshub (Ang. -Sax.) (Leuciscus cephalus), of the same genus with the roach, dace, bleak, &c. It is plentiful in many of the rivers of England and of the south-west of Scotland. The chub rises freely at

variety of baits, - slugs, grasshoppers cockchafers, and humble bees among the number. The best place to fly-fish for chub is close under overhanging trees, by the sides of

streams, or against piles or other places that offer ready shelter. The chub spawns in May, and comes into condition again about the end of June or beginning of July. It bites freest, and is in the best condition for bottom-fishing, between the middle of October and November. The colours of the chub are blue-black

and November. The colours of the chub are blue-blank on the upper part, silvery white below; cheeks and gill-covers golden yellow. Weight seldom exceeding five pounds. Is not considered a great dainty.

Church, Isharish (Ger. kircke, Dan. kirke, Scotch kirk), in generally supposed to be derived from the Greek kuriakon, belonging to the Lord; from kurios, Lord. In its widest signification, the term Church is applied to the whole collective body of those who profess to be followers of Jesus Christ, and hence denominated by ancient writers the Catholic or Universal Church. The assembly of the faithful upon carth is sometimes called the church militant, as distinguished from the church triumphant, the faithful already in glory. In a more limited sense the term is already in glory. In a more limited sense the term is applied to a body of Christians differing in its constiapphed to a body of Christians differing in its constitution, doctrines, and usages from the rest; as the Roman Church, Greek Church, Reformed Church. In another sense it is applied to the whole Christian community of a country, or to the established refigion of a country; as the Gallie Church, Church of England, Church of Scotland. In a still more limited sense it is applied to a particular congregation of Christians, who associate together and participate in the institutions of Christ with their proper Dasture unristians, who associate together and participate in the institutions of Christ with their proper pastors and ministers. It also signifies the building in which Christians assemble for the worship of God.

Church, in Arch., the name given to a building especially set spart for the worship of God.

## Church, Greek

models after which churches are principally built are those of the old Roman basilies (see Basilies), and the cruciform plan adopted in Byzantine architecture (See BYZANTINE ABCRITECTURE,) Churches are di-(See BYZINTIM ARGHITECTURE) Churches are divided into five classes:—1. Metropolitan churches, or the principal churches in the sees of archbishops; 2. Cathedral churches (see CATHEDRAI); 3. Collegiste churches, or churches that have a chapter of canons, but no bishop; 4. Conventual churches, or churches attached to a monastery under the superintendence of an abbot; and 5. Parish churches. The first four classes are more ornate in character, and are considerably larger than the fifth, and have numerous chargeds and aisless attached, which are not to be found in the pagish church. The cathedral church, so called because it contains the throne of a bishop, which has because it contains the throne of a bishop, which has been described in a preceding article, may be taken as the general type of these four classes. The parish church, particularly those built prior to the date of the church, particularly those built prior to the date of the Enformation, is generally built in the form of the Latin eroes, with the nave much longer than the arms, forming the transpots and clory, or chancel. Those of the 18th century are, for the most part, built in imitation of the old Greek temple, a style utterly unsuited to a Christian church; but in the 19th century, a tendency is shown to imitate the purer Byzautine form of church exhibite transport in the chiracters and to build the churches more in the architecture, and to build the churches more in accordance with the form of the Greek cross, in which the nave, transcots, and chancel, are of equal length. The principal part of our old parish churches belong to the Anglo-Norman, Early Perpendicular, and Decorated forms of English architecture. At the west end stands a massive tower with a belfry, buttressed and finished with battlements and pinnacles; but sometimes the belfry is in a tower built on arches at the intersection of the arms of the cross, which is often sur-mounted by a spire. The body of the church consists of a nave, separated from the side aisles by rows of of a nave, separated from the side aisles by rows of pillars. The principal entrance is generally on the south side. The transepts are small, and in some churches there are none, or only one small transcept on the south side, and one aisle to the nave. The chancel is separated from the nave by a screen carved in wood. The communion-table stands at the east end of the chancel, inclosed by rails. The vestry is usually found on the north side of the chancel, and the reading-desk and pulpit before the screen in the nave, sometimes on the north side and together, and at other times, one on either side of the central passage running through the church. The font stands at the west end, opposite the mouth porch. There is a gallery at the west end of the majority of churches for the choir and organ, if there be one. The nave and aisles are usually divided into a number of pews, resembling loose boxes; but these are practically being removed, and long low pews, or open benches, are substituted for them wherever the in-terior of a church has been beautified and restored. The windows consist, for the most part, of lozengemed panes in easement-lights, set in stone mullions.

CHURCH, GREEK. (See GREEK CHURCH.) CHURCH OF ENGLAND. (See ANGLO-CATHOLIC

CHURCH OF ROME. (See ROMAN CATHOLICISM.)

CHURCH OF SCOTLAND. (See SCOTLAND, CHURCH OF.)
CHURCHING OF WOMEN, tshurtsh'-ing, is a public
and solemn acknowledgment enjoined by the Church to be made by a mother, after childbirth, of the blessing that has been vouchsafed to her. It doubtless owes its origin to the Jewish rite of purification enjoined by Moses, and complied with by the Blessed Virgin; but it is not regarded by the Church as a purification, but as a thankagiving to God for a mer-efful deliverance. The office is of great antiquity, and is found in the ritual both of the Western and

Eastern churches.

Office Charles. (See Taxes and Rates.)

OHURCHWAUDENS, tehurtsh-waur'. dens, formerly called sharch-reves, or ecclesia guardians, are the guardians or keepers of the church, and the legal representatives the body of the parish. They are chosen annually the parson and his parishioners, according to the om of the place, and their duties are to look after the church, church, represented &c.; to observe the behaviour of the parishioners with regard to such faults as come under the jurisdiction of the ecole-

### Cichorium

stastical court; to take care that none preach without a license, &c. They constitute a kind of corporation, and are enabled to sue and to be sued at law.

CHURCHYARD, takurtah'-yard, is the ground ad-joining to the church, in which the dead are buried. (See BURIAL.)

(See BURIAL.)
CHUCKYARD BERTLE. (See BLAFS.)
CHUTKEE, taket'-nee (its Indian name), a condiment
very largely consumed in India and Great Britain.
There are many varieties of chutnee, but it generally
consists of a compound of mangoes, capsicum or chillies, and lime-juice, flavoured with garlic and eschalots. Several native fruits, such as tamarinds, are often added to East-Indian chutnec.

CHYLE, kilo (Gr. chulos, juice), is the milk-like fluid which is formed by the action of the bile and pancreatic juice upon the chyme in the duodenum, and absorbed by the lacteal vessels. The use of the chyle is to apply the matter from which the blood is formed and the veste of the kiling areas a result of the chyle is to apply the matter from which the blood is formed and the

waste of the living organs repaired. (See Digestron.)
CHYME, kime (Gr. chumos, juice), is the ingested
mass formed by the action of the stomach upon the food, and which passes from the stomach into the duo-denum. (See DIGESTION.)

CIHORIUM, ei-bor'-i-nm, was a name originally given to the husks of an Egyptian bean, and came afterwards to be applied to the canopy with which the altar was The term is also applied to the pyx or box in which the host is preserved.

CIBCTIUM, si-bo'-te-um, in Bot., a gen. of ferns, nat. ord. Filices, including several species which produce silky hairs useful to man. The styptic called penawar, which is often used in Holland and Germany, consists of the fine hairs from the caudex of C. Burn-metz, the "Scythian lamb" of old writers. These hairs are imported from Sumatra, and are sometimes em-ployed for stuffing cushions. Similar hairs are brought from the Sandwich Islands, and are known under the name of pulu. Three different species are said to yield

CICADA, se-kai'-dā (Lat., grusshopper), a gen. of insects of the ord. Hemiptera, common in tropical and warm temperate regions, and remarkable for the loudeness of the sounds they emit. The organs that produce these shrill sounds consist of membranes and fibres these shrill sounds consist of membranes and norse connected with powerful muscles, and situated on the under-side of the abdomen. The largest insect of this genus does not exceed an inch in length; yet it is asserted that they may be heard in the still night at a distance of at least half a mile, and that the sound they contribulity similars briften a relative to emit is like grinding a knife on a whetstone.

CICATRIZATION, sik'-a-tri-zai'-shun (Lat. cicatrico, I heal up), is a term in Surg., applied to the healing or skinning over of an ulcer or broken surface of the skin.

CICER, si' ser (from Gr. kikvs, strength, in reference to its qualities), in Bot., a gen. of plants belonging to the nat. ord. Leguminione, cub-ord. Papilionacca. C. arictinum, a native of the countries around the Mediterranean, produces the edible seeds called chick-peas. These are extensively used as food, either boiled or roasted, and are the most common parched pulse of the East. The herbage affords a nutritious food for cattle.

CICERONE, tellsh-e-rof-ne, a name first given in Italy to those persons that act as guides to strangers in showing them the sights of Rome and other cities. The term is said to be derived from Cicero, and to have been given to them on account of their great garrulity. The word has now come into general use, and is applied to any one who points out the interesting objects of a town to strangers.

CICHORIUM, si-kor'-e-um (Lat.), in Bot., a gen. of plants belonging to the nat. ord. Composita. The species C. Litybus is the wild chicory or succory, a plant indigenous to this and many other countries of Europe, having numerous heads of bright-blue handsome flowers. It is extensively callivated for the sake of its roots, which are sliced, roasted, and ground, to form the chicory of the shops, which is sold as a substitute for, or more frequently as an addition to, ground coffee. Nearly 100,000,000 lbs. are annually consumed in Europe. Much of the chicory used in Britain is of home growth; but still more is imported in the raw state from Holland and other parts of the continent. Though so extensively used instead of coffee, chicory

### Cicindelide

does not possess in any degree the peculiar exciting, soothing, and hunger-staying properties of that valuable product. The fresh root has been employed in medicine to produce similar effects to those produced by the dandelion root, (See Taraxacum.) A blue dye may be prepared from the leaves. C. Endiva is the garden succory or endive, the leaves of which, when blanched, form a wholesome salad.

CICINDELIDE. (See TIGER-BHETLES.)
CICISBEO, tshe-tshiz-beo (Ital., a gallant), is a term spylied to a class of persons in Italy who constantly attend upon murried ladies. In the higher ranks of society it was formerly the custom for every married society it was formerly the custom for every married lady to have her ciciebeo, who escorted her in her walks, and accompanied her to private parties and public amusements. The practice has now almost entirely disappeared.

CICUTA, si-ku'-tu, in Bot., a gen. of plants belonging to the nat. ord. Umbellifera. C. virosa, the waterhemlock, or cowbane, is a common indigenous plant of birth pricepones autome. C. secondade a native of

of a highly poisonous nature. C. maculata, a native of America, has very poisonous roots, which, from having been mistaken for those of harmless Umbellifera, have

been mistaken for those of narmies Conventyers, have not unfrequently led to fatal results.

Cm, sid (Arab. scid, lord), is the name of an epic poem of the Spaniards, celebrating the exploits of their great national hero Roderigo Diaz, commonly called the Cid. The poem is supposed to have been written in the 12th or 13th century, but nothing is known of the collection.

its author.

CIDER, or CYDER, si'-der (Fr. cidre), the expressed and fermented juice of apples. The apples are thrown into a circular stone trough, and bruised by a heavy round stone turned by horses, until the whole are reduced to a pulp called "must." The must is then spread upon a haircloth, several of which are piled together and placed under a screw press; the screw is turned slowly, and the juice exudes, flowing into a flat tub; from this it is poured into casks placed in a position where there is a free current of air. The inquor ferments, and the clear cider is drawn off from time to time: this is again racked until it is perfectly The fermentation of cider is a very difficult process, requiring great experience to determine when it is going on too slowly or too quickly. In England, cider is made principally in the Herefordshire district, where the above method of pressing is adopted, and in Devonshire, where a screw press of rude form is employed. Cider requires great care in keeping, being apt to turn sour, and has lately fallen into disuse on account of great quantities of "doctored" sour cider having been retailed by dealers and publisour cider having been retailed by dealers am puni-cans. Cider is also made in Normandy, Belgium, and Germany. A powerful spirit is obtained from cider by distillation.—Ref. Callivation of Orchards and Making of Culer and Perry, by Falkner. CIGAR MANUFACTURE. (See TOBACCO MANUFAC-

TURE.)

CHIUM, sill-i-um (Lat.), is a name given in Anat. to the eyelid or eyelash; and hence the term ciliary is applied to the arteries, glands, &c., belonging to

the eyelids.

CINCHONA, sin-ko'-na (named after the Countess del Cinchon), in Bot., the typical gen. of the nat. ord. Cinchonacea. The plants of this genus are natives of the intertropical valleys of the Andes, and are found principally on the eastern face of the Cordilleras, component the circumstance of the Cordilleras, growing commonly at heights varying from about 4,000 to nearly 12,000 feet above the level of the sea. The cinchona region extends from Santa Cruz de la cherra, in Bolivia, about 19° S. lat., through Peru and Columbia, nearly to Caracas, in about 10° of N. lat. The plants are small shrubs or large forest-trees, with appear to require great moisture, and a mean temperature of about 62°. The cultivation of these plants has lately been commenced in India. The barks of several species and varieties are extensively used in medicine. and are undoubtedly the most valuable drugs known. They are imported into this country under the names of Cinchona, Peruvian and Jesuita' bark. Twenty six different varieties have been described by Pereira; and Wedgell has enumerated no less than thirty-nine. The most important are Loxo, or crown bark; grey, silver, or Huanuco bark; Calisaya, or yellow bark; 507

### Cinnamomum

and red bark. These four are officinal in our phar copesias, and are the principal sources of the pre-alkaloids quina or quinine, ciuchonia, and quisi which are all used in medicine, and possess in eminent degree tonic, febrifugal, and antiper properties. The barks themselves have similar properties. Like Darks themselves have builded perties, and are, moreover, slightly astringent, name compliment to the countess of Cinchon, whose band was the viceroy of Peru. She had derived band was the viceroy of Peru. She had derived benefit from the bark during her residence in America; and on her return to Europe, in 1639, the brought with her several specimens. The native scientific one, being gunguino and guna-quino. The medicinal use of the bark was first made known in Europe by the Jesuits. (For a full account of the numerous varieties of cinchons bark found in commerce, see Royle's Manual of Materia Medica.)

CINCHONACEE, sin-ko-nai se-e, in Bot., a nat. ord. of dicotyledonous plants in the sub-class Corolliform, including about 2,550 species, which are grouped into alls genera. They are trees, shrubs, or herbs, with opposite, simple, entire leaves, and stipules between the leaf-stalks on each side (interpetiolar). The estyr is superior, the corolla regular; the stamens are equal in number to the teeth of the calyx and see ments of the corolla, being alternate with the latter; they are attached to the corolla (epipetalous). The overy is inferior, and 2- or more celled; the fruit inferior, with one seed, or sometimes more than one The Cinchonacea are almost exclusively natives of tropical and warm regions. They yield many valuable medicinal agents, the most important being quining (see CINCHONA) and ipecacuanha (see CEPHARLIS). They also furnish man with many substances useful in the arts and domestic economy; such as dye-stude, tanning agents, edible fruits and seeds, and ornamental woods. The collec-plant belongs to this extensive order. (See Correlation) Most of the plants have been tiful and fragrant flowers, and many have been introduced into our stoves.

CINCINNATI, The, sin-sin-näll-s, was a society or order of certain officers of the United States army, established in 1783, with Washington at their head-They took their name from Cincinnatus, the Romain general who left the plough to defend the state. As the order was made hereditary, it was regarded by many as contrary to the spirit of republicanism, and

became so unpopular that it at length ceased to exist.

CINERARY URNS. (See VASES.)

CINERARY, sin'-na-bar (Gr. kinnabari), the principal ore of mercury, from which the greater proportion of all the mercury of commerce is obtained. It is a bisulphuret, and contains 86.2 parts of mercury and 13.8 parts of sulphur. Native cinabar is found mas-sive and crystallized in six-sided prisms, rhombs, and octohedra. It is of various colours, sometimes appearing steel-grey, and at others bright red. It is not found in Britain, but occurs in France, Hungary, and Spain, in Siberia and Japan, and in large quantities in South America. It has also been imported from China. Native mercury and native amalgam of silver are sometimes found accompanying cinnabar. Under the name of vermilion, cinnabar is used as a pigment, when refined. Hepatic cinnabar is a variety containing a little carbon, and so called on account of its liver-brown colour, from the Greek word hepar, the liver.

Cinnamonum, sim-dimo'-mum (Lat.), in Bot., a gen. of plants belonging to the nat. ord. Laurasea,

including many species remarkable for their aromatio niciding many species remarkants for their arounds properties. C. zeylanicum, the cinnamon-tree, a native of Ceylon, is extensively cultivated in that island, also on the Malabar coast, in Java and Cayenne, for the sake of the aromatic bark of the young branches, which forms the true cinnamon of commerce. Cinnamon of commerce of medicinally see mon is much employed as a spice, and medicinally as a cordial, stimulant, carminative, astringent, antispas-modic agent, and as an adjunct to other medicines. It owes its properties to the presence of a volatile oil and tannin. The volatile oil is imported from Ceylon, where it is obtained from the rejected bark by distillation. It is known by the name of oil of cinnamon, and is used medicinally aspa stimulant, and by cooks and confectioners for flavouring. From the leaves of the

PRIVE STATE

### Cinnanton

tree another volatile oil, similar to oil of cloves in odour and taste, is prepared. From the ripe fruits a concrete fatty substance called cinnamon suct is ob-

twined by expression. The cinnamon-tree is the kinnemon or kin-man of the Bible, C. cas-sia, a native of China, yields the cassia bark of commerce, which possesses analogous possesses properties to those of From this cinnamon. bark the fragrant oil of cassia is obtained. The cassia buds of commerce, which are now much used as a condi-ment, are said to be the flower-buds of this

plant. The cassis-tree plant. The cassis-tree plant. The cassis-tree points of the Bible. Several other species of cinnumomum yield aromatic barks.

CINHAMON. (See CINHAMONUM.)
CINNAMON. (See CINHAMONUM.)
CINNAMON. STORE, sin'-nō-mon, a species of garnet, also called essonite, of a light cinnamon-yellow colour and high lustre. If carefully cut and skilfully polished it commands a good price. It is a silicate of alumina and lime. (See GARNET.)
CIPHUR, si-fer (Arab. sifr, empty or destitute of, is a term applied to the figure 0. It is sometimes also applied to a swithwaters' conventily.

applied to arithmetical characters generally; and hence the verb "to cipher" signifies to perform an arithmetical operation. A cipher is also a funciful arrangement of the initials of a name, sometimes adopted by artists and others in order to distinguish their works.

Circus, ser'-kl (Fr. cerele, Lat. circulus), in Geom., is, according to Locke's definition, "a line continued till it ends where it began, having all its parts equidistant from a common centre." The bounding line distant from a common centre." is called the circumference or periphery. Any straight line drawn through the contre and terminating in the and drawn through the centre and terminating in the circumsterence is called a diameter. The circle is one of the elements of plane geometry, the right line being the other; and those constructions only are regarded as geometrical which can be made by the aid of these two elements. The circle, however, derives its chief importance from its application in trigonometry to the measurement of angles. This application is dependent on the fact, that if circles of the same radii be described from the vertices of angles as centres, the arcs of the circles intercepted between the sides are always pro-portional to the angles. It is for this reason that the circle is almost aways employed to compare angles with each other. For this purpose the circumference of the circle is divided into four equal parts, each of

of the circle is divided into four equal parts, each of which is called a quadrant; ench quadrant is divided into ninety equal parts, called degrees; each degree is divided into sixty equal parts, called minutes; each minute into sixty equal parts, called seconds.

CIRCLE, in Log., is applied to a kind of false reasoning, in which the principle is supposed which it is intended to prove, and afterwards the principle is proved by the thing which it seemed to have proved. The same fault takes place in definitions, when an idea is defined by others which suppose the knowledge of the first. the first

OTHERE, MAGIC, the circle or space within which magicians work their enchantments, and which are believed to protect them from the evil spirits which they raise. A piece of ground is usually chosen, nine feet square, at the full extent of which parallel lines are drawn, one within the other, having sundry crosses and triangles described between them, close to which is formed the first or outer circle. About half a foot within the same a second circle is described, and within that another square space corresponding to the first, and in the centre is the seat or spot where the master and his associate place themselves.—Ref. Smedley's

### Circumoision

the Norfolk, the Oxford, the Northern, the Western, the South-Wales and Chester, and the North-Wales

und Chester. (See Assize.)
Cincular Norks, sir-ku-lar notes, are a kind of bank-notes, issued by certain of the London bankinghouses for the convenience of travellers. They are each of the value of £10 or upwards, and along with them the traveller receives a list of the agents in the different places where they may be cashed. The great advantage of these notes is, that the traveller may exchange one or more of them at different parts of his route, and receive their full value in the money of the country, without any charge for commission.

CIRCULAR SAILING. (See NAVIGATION.)

CIRCULATING LIBRARY. (See LIBRARY.) CIRCULATING MEDIUM, sir-ku-lai'-ting me'-di-um, in Pol. Econ., is the medium by which exchanges or purchases and sales are effected, whether that he gold or silver coin, paper, or any other article employed as the measure of the value of other things. It is scarcely possible to imagine a people living without a circulating medium of some kind; and accordingly we find, even among the most savage tribes, some articles to which they refer as a measure of wealth, whether these be slaves, skins, or cowry-shells. (See CURRENCE.)

CIRCULATION OF THE BLOOD, sir-ku-lai shun (Lat. circulus, a circle), in Physiol., is applied to the course of the blood through the body, from the heart to the capillaries, and from the capillaries back again to the heart. The several organs of circulation are the heart arteries, veins, and capillaries. By the heart the blood is propelled through the arteries to all parts of the heart the blood. body. The capillaries are very minute vessels, con-necting the extremities of the arteries with those of the veins, and by the veins the blood is returned again to the heart. The heart is composed of two distinct cavities, separated from each other by a partition or septum, and termed the right and left sides of the heart; the right being also termed the venous or pul-monic heart, the left the arterial or systemic heart. Each of these sides is subdivided into two cavities, the superior being termed the suricle, the inferior the ventricle. The blood which has been distributed by the arteries through the different parts of the body, passes from them, by means of the capillaries, into the The veins from the lower part of the body veius. empty themselves into the inferior vena cava, and those from the upper part into the superior vena cave, and both pour their contents into the right auricle. This contracts, and forces the blood into the right ventricle, contracts, and forces the blood into the right ventricle, which, in turn, forces it through the pulmonary artery to the lungs, where, by the action of the air, the venous blood is purified and changed into arterial. It is then conveyed by the four pulmonary veins into the left auricle, whence it passes into the left ventricle, from which it is propelled into the aorta, and by this means distributed to all parts of the body. The pulse which is felt in the arteries is caused by the action of the heart propelling the blood in wayse through the heart. heart propelling the blood in waves through the body. The discovery of the circulation of the blood is due to Dr. Harvey, afterwards physician to Charles I.; the opinion previous to his time being, that the blood circulated only in the veins, and that the arteries, from being always found empty after death, contained nothing but air; and hence their name.

Checumension, sir-kum-sir-zhun (Lat., a cutting round), is the cutting off the prepute or foreskin,—a rite common among eastern nations, both ancient and modern. Abraham was commanded by God to circumcise himself and all the males of his household, and to transmit the custom to his posterity. It took place on the eighth day after birth, and is still very sorupuon the eighth day after birth, and is still very sorunu-lously observed by the Jews. There is indubitable evidence to show that the rite was practised by the Egyptians long before the time of Abraham; and Herodotus and others mention its having been prac-tised among various ancient nations. In modern times it has been found practised through a great part of Africa and Asia, and even in Mexico, the West Indies, and various parts of South America. Among the Mohammedans, as well as by the Jews, it is regarded as a religious rite. Circumcision was established among Occult Sciences.

Ozours, sir-kits (Fr. circuit, Lat. circuitus), are the Home, the purpose of an archigious rite. Circumoision was established among right divisions of the kingdong, for the purpose of and his seed; and it was declared that "the uncircumbolding the serizes. They are the Home, the Midland, cised man child whose skin of his foreskin is uncircum-

# Circumcision, Feast of

cised, that soul shall be cut off from his people; he hath broken my covenant."

CIRCUNCISION, FRAST OF, is a festival observed by the Church in commemoration of the circumcision of

Jesus Christ, held on the eighth day after Christmas, or

the 1st of January.
CIECUMPLEX sir'-kum-flex (Lat. circum, round, and flecto, I bend), in Gram., is an accent marked thus A, and is placed over a syllable to denote that its sound and is placed over a syllable to denote that its sound is intermediate between acute and grave. It is seldom used in the present day except to show the omission of a letter, which makes the syllable long and open; as Bâle for Basle.

CIRCUMLOCUTION, sir-kum-lo-ku'-shun (Lat. circum, and loguer, I speak), is a circuitous mode of expression, used either when the proper term for expressing an idea does not naturally and immediately occur, or

when a person wishes to avoid expressing in direct terms something disagreeable or inconvenient.

CIRCUMSTANTIAL EVIDENCE. (See EVIDENCE.)
CIRCUS, ser-kus (Lat.), a large inclosed space, of colong form, adapted for horse and chariot racing, sports to which the encient Romans were much adsports to which the encient Romans were much addicted. The circus was also used for athletic games and the contests of wild beasts. There were many buildings of the kind in Rome, of which the Circus Maximus and Circus Agonalis were probably the largest. According to different authorities, the former margest. According to different authorities, the former was capable of holding between 200,000 and 400,000 speciators. The Circus of Nero was begun by Caligula; part of its site is now occupied by the Basilica of St. Peter. All the circi which existed in ancient Rome are completely destroyed; but near the tomb of Cocilia Metellus, not far from the Appian Way, about two miles from Rome, there is a circus, commonly called the Circus of Caracalla, in a high state of pre-servation; it is small in size, but probably resembles servation; it is small in size, but prousby resembles closely the larger circ in general form. In length, the Circus of Caracalla is about 1,300 feet, and 300 feet wide. The long sides are not quite parallel; one end is semicircular, and the carceree, or covered stalls, furnished with gates, are there eituated. In the carceres the chariots and horses remained till the starter gave the signal, when the gates were opened. Along the sides, and round the opposite end from the carceres, were ascending ranges of stone seats for the spectators. There is a bas-relief in the British Museum which gives a very tolerable notion of the appearance of an ancient circus. The modern circus does not resemble that of the ancients; it is small in size, and is generally a temporary erection, consisting of a ring surrounded by raised seats for the spectators. The principal amusements are feats of horsemanship and acrobatic displays.

CISSAMPELOS, sis-sam'-pel-os (Gr. kissos, ivy; ampelos a vine), in Bot., a gen. of plants belonging to the nat. ord. Menispermacea. The root of C. Pareira, a climbing plant indigenous in Brazil, is an article of our Materia Medica, and is commonly known as Pareira brava. It possesses bitter, tonic, and diuretic properties, which are chiefly due to the presence of an uncrystallizable

alkaloid named cissampeline or pelosine.

CISTACRE, sis-tai'-se-e (Gr. kiste, a box or capsulc),
in Bot., the Rock-rose fam., a nat. ord of dicotyleonous plants in the sub-class Thalamiform, consisting of seven genera and 185 species, chiefly natives of the south of Europe and north of Africa; they are shrubs or herbs. The leaves are entire; the are shrubs or herbs. The leaves are entire; the senals and petals have a ternary or quinary arrangement, and are twisted in astivation, the former being persistent and the latter caducous; the stamens are hypogynous and distinct; the overy has perietal placontas, and a single style with a simple stigma; the fruit is capsular; the seeds have mealy albumen and embryos inverted, curved, or spiral. The Cistacca have resinous and balasmic properties. From species of the

# Oltizen

and was so called from having its first establishment at Citeaux (Cistercium). Through the exercions of St. Bernard of Clairvaux and others, this order had increased in power so rapidly, that within a hundred years creased in power so rapidly, that within a number years of its foundation it embraced 800 nch abbygin different parts of Europe. It became so powerful, that it governed almost all Europe, both in temporal and spiritual concerns. The Cisterians dedicated themselves to a contemplative life, and their rule was severe. Cardinal De Vitry says they neither wore skins nor shirts, nor ate flesh, except in sickness, and abstained smrts, nor are near, except in stokness, and anstance from fish, eggs, milk, and cheese. They lay only on straw beds, in their tunics and cowls; rose at midnight and sang praises to God till break of day; spent the day in labour, reading, and prayer, and in all their exercises observed a strict and continual silenes. Towards the end of the 12th century, however, riches and indolence began to operate unfavourably on their discipline, and led the way to great corruptions. Many of the convents had ceased to exist before the Reforma tion, and many more speedily after that event. In the reign of Edward I, there were sixty-one Cistercian monasteries in England. The habit of the order is a white robe or cassock, with a black scapulary and a woollen girdle. Many eminent men have sprung from it.

(See WATER SUPPLY.) CISTERN.

CITATION, si-lai-shun (Lat. cilatio), a summons to appear, applied particularly to process in the spiritual courts, where they proceed, according to the course of the civil and canon laws, by citation.

CITHARA, sith'-a-ra, an ancient musical instrument, supposed to have resembled the lyre; its precise con-struction, however, is now unknown. The cithera had struction, however, is now unknown. at first only three strings; but the number was increased at different times to eight, nine, and, lastly, to twenty-four.

Cities of Refuge, sit-ees, were six cities (three on each side of Jordan) which God commanded Moses to set up for a refuge for the children of Israel, and for the stranger and for the sojourner among them. that every one that killeth any person unawares might fee thither, and find refuge from the avenger of blood. The manslayer was to remain there until the death of the high priest, after which he could return to his own land. They were Hebron, Sheehem, and Kadesh-Naphthali on the west side of Jordan, and Bezer, Ramoth-Gilead, and Golan on the east. It is said that at every cross-road signs were set up, pointing the way

to the cities of refuge.

CITIZEN, sit-i-zen (Fr. citoyen, Lat. civis), is, by
Aristotle, defined to be one who participates in the judicial and legislative power in a state; and in this sense it could only be applied in those states in which the people had some share in the sovereign power. In ancient Greece and Rome, citizens enjoyed numerous important privileges and immunities, which they watched over with the most jealous care. Among the rights enjoyed by Roman citizens was that of holding rights enjoyed by itoman cluzens was that of holding public offices in the state; of voting in the public assemblies of the people; of appealing to the people against any sentence of the magistrates, or act of oppression on the part of others; of making a will, and succeeding to an inheritance; and of having the power of life and death over their children. No magistrate could order a Roman citizen to be put to death, por to could order a roman citizen to be put to death, nor to be punished by stripes. Citizenship was only obtained by birth, or conferred by a public act. Noterm of residence, or the circumstance of being born in the city, conferred that right. Neither could any one claim citizenship by birth unless he was born of such a marriage as the state considered legal,—all marriages between citizens and freed slaves, or their descendants, between citizens and freed slaves, or their descendants, were illegal. To be a citizen, it was necessury to be an inhabitant of Rome, to be enrolled in one of the tribes, and to be capable of dignities. There was also a lower class of citizenship, which conferred no right of voting or of holding public office. The practice of admitting aliens (peregrini) to the rights of citizenship became more and more common as their territories extended; and at length the emperor Caracalla granted the freedom of Roman citizens to all the inhabitants of resinous and balsamic properties. From species of the typical genus Cistus, a fragrant resinous substance, a lower class of citizenship, which conferred no right called Ladanum, is obtained in the Levant. This is need medicinally as an expectorant and emmenagoue, and is much esteemed by the Turks as a perfume. A gum called Kuteera, which is sometimes substituted in India for tragacanth, is the Froduce of a plant of this order, named Cochoppermum Gosuppium.

CISTERGIAES, sis-ter'-st-ins, a religious order originally established by St. Robert, abbot of Molesme (1068),

500

### Citric Acid

well as to all persons who are born anywhere of a British citizen, or of one whose father, or father's father, was a citizen of Great Britain. Commonly the term citizen is employed to denote the inhabitant of a town. In France, a citizen is one who has been born in the country, or is naturalized in it.

Cirric Acid, et frik, a powerful tribasic acid, found principally in the lemon, lime, orange, and other members of the Aurantiacea fam. It also occurs in other acid fruits, such as the gooseberry, raspberry, strawberry, and tamarind. It is procured by neutralizing lemon or lime juice with chalk, and decomposing the insoluble citrate thus formed with sulphuric acid. Citric acid is very soluble in water. It crystallizes in transparent colourless rhombic prisms, which have an agreeable acid taste. Citric acid is a tribasic acid, and forms three citrates of soda, for instance, containing one, two, and three equivalents of acid united to an equivalent of base. The alkaline citrates are all soluble in water; so also are many of the metallic citrates. The most important of these is the citrate of lime, by the decomposition of which citric acid is formed.
When subjected to destructive distillation, citric acid undergoes a remarkable change. It first melts, and parts with its water of crystallization. At 350° Fahr, decomposition commences, guses are given off, and the residue consists of acontic ucid, an acid found and the residue consists of aconstic acid, an and found in aconite. If the heat be continued, staconic acid is formed. Citric acid may be looked upon as the hydrated teroxide of cetryl, a hypothetical radicle. Citric acid is very valuable as a mordant in calicoprinting; it is also used in pharmacy, in the manufacture of lemonade and syrups, and occasionally in photography. Combinations of citric acid with iron and armonic are much used in medicine. It is also and ammonia are much used in medicine. It is also used in the preparation of effervescing draughts. The antiscorbutic properties of lemon-juice are due to the presence of citric acid. (For a detailed account of the combinations and derivatives of citric acid, the reader is referred to Gerhardt's Traité de Chimic.)

CITRINULUS, OF CITRINUS, sit-ri'-nu-lus, si-tri'-nus, old names for a kind of stone between a crystal and a beryl, formerly called saxifragus, and believed to be lithestriptic.

CITRON, OIL OF, sit'-ron, a fragrant oil procured by distilling the flowers of the Citrus medica, much used

in perfumery.

CITRONELLE, OIL OF. (See ANDROPOGON.)

CITRUS, 8i'-trus (said to be from the town Citron, in Judes), in Bot., a gen. of plants belonging to the nat. ord. Aurantisacco. The different species and varieties of this genus yield the fruits known under the names of orange, lemon, lime, shaddock, pompel-moose, forbidden fruit, kumquat, and citron. The species C. Aurantium, and its varieties, produce all the various descriptions of sweet oranges, the most important of which are the St. Michael's, the blood-red, the Maltere, and the common oranges. They are imthe Malters, and the common oranges. They are imported in immense numbers from the Azores, Lisbon, Malta, and Sicily. C. Bigaradia, or vulgaris, yields the bitter, or Seville orange. The orange-tree is remarkable for its prolificness: thus, a single plant will sometimes produce as many as 20,000 good oranges. The small unripe fruits of C. Awantium, as well as those of C. Bigaradia, are used for flavouring Curaçon, being called orange-berries; when polished in a lathe they constitute the ordinary usue peas of the shops The leaves of both species, when distilled with water rield a volatile oil, which is called oil of orange-leaf, or seems de petit grain. Their flowers yield the fragrant oil known as oil of Neroli, which is the most important ingredient in eau de Cologne. The distilled water of the flowers is named orange-flower water. By distilling the rind of the ripe sweet orange with water, a fra-grant oil, named essential oil of sweet orange, is ob-tained. The rind itself is used in medicine as an arotained. The rind itself is used in medicine as an aromatic, stimulant, and tonic. The juice of the fruit forms matic, stimulant, and tonic. The juice of the fruit forms a refreshing beverage, and in medicine a valuable refrigerant. The bitter orange is chiefly used for making marmalade. Its rind yields a volatile oil called essential oil of bitter orange, and is used medicinally, and two making condicat orange-peel. C. Limonum and its varieties produce the fruits called lemons, the chief varieties of which are the wastemon, the imperial bemon, and the Gasta lemon. They are chiefly im-

#### Civat

ported from Sicily and Spain, those from the latter country being most esteemed. Both the rind and juice are employed in medicine, the former as an aromatic and stomachic, and the latter for its re-frigerant and antiscorbutic effects. The juice con-tains a large quantity of citric acid, and is extensively used for flavouring and to form the refreshing beverage

called lemonade. The rind contains a large quantity of essential oil, which is obtained from it by expression or by distillation, and is known as the essen-tial oil, or essence of lemon. This oil is principally used as a flavouring agent in confectionery and in me-dicine, and occasion-ally in perfumery. Candied lemon-peel is a common ingredient in puddings and cakes. C. Limetta is the source of the lime. This fruit is generally imported into this country in a preserved state, and in

CITRON.

that condition it forms a most agreeable dessert. juice is also imported, and largely employed, with that of the lemon, in the preparation of citric acid. C. medica yields the fruit called the citron, which is supposed to be the Hebrew tappuach. This word is translated in the English version of the Old Testament as "apple." The rind of the citron is imported in a pre-served state, and is used in confectionery. The pulp is less acid and juicy than that of the lemon. Two essential oils used in perfumery are obtained from C. medica. They are named respectively essence, or essential oil of citron, and essence of cedrat, or cedra. The citron, lime, and lemon, are distinguished from the orange by The citron, their adherent rinds, their more lengthened form, and by the occurrence of a more or less preminent protuberance at the apex. C. Bergamia, which yields the Bergamot orange, so largely used in perfumery, is generally regarded as a mere variety of C. Limetta. (See BERGAMOT.) Besides the above fruits obtained from the genus Citrus, we have the shaddock, from the species. C. decumana; the forbidden fruit, from C. Paradisi; the pompelmoose, from C. Pampelmos; and the kum-

quat of China, from C. japonica.

CITY, sit'-e (Fr. cité, Lat. civitas), is applied to certain large and important towns, both in England and other countries. It is commonly said that a city is a borough or a town-corporate, which is or has been the seat of a bishop; but this is not strictly correct, for there are many examples of towns in England which were once the seats of bishops, which are never called. cities. The term seems rather to have been anciently applied as complimentary to certain towns of principal note and importance. A city differs in no-respect, except that of superior dignity, from an or-dinary borough.—Ref. English Cyclopadia—Arts and

CIVET (Viverra), siv'-et, a native of North Africa. Its size is about two feet six inches in length, and ten or twelve inches in height; head long; muzzle sharp, as in the weasel; a narrow bristly mane runs from the pole of the neck to the tail. Its colour is brownish grey, with black bunds and spots. It is a carnivorous animal, and preys on birds, small quadrupeds, and rentiles. The true civet's most remarkable feature consists of a sort of pouch between the anus and sexual organs, in which collects an odorous liquid of considerable value in the perfume-market. For the sake-of this it is very commonly kept in confinement. The perfume is removed from the pouch about twice a week. The quantity yielded is about a dram at each removal. Great care has to be observed during the pouch-emptying process; for the civet has a decided objection to it, and will struggle its hardest to avenge itself on the operator. Whether the ferocity of the true civet is caused by their anxiety about the safe-keeping of their secretions, cannot, of course, be explained; but it is

#### Civet

certain that those who, on account of the valueless contents of their pouch, are not operated on, are com-

paratively of amiable disposition, and will even become domesticated.

CIVET, a substance secreted by the Viverra civetta, or divet-cat. In any quantity the odour is over-poweringly disgusting; but, diluted infinitesimally, its perfume is most agreeable. It is extensively used by Parisian perfumers, but the English manufacturers

rarisan pertuners, but the English manufacturers prefer the use of musk.

Civic Crown. (See Crown.)

Civic it (Lut. civilis, from civis, a citizen), that which relates to the community, or to the policy and government of the citizens and subjects of a state.

CIVIL DEATH, is where a man, by an act of parlinment or judgment of law, is attainted of treason or felony, by which he loses his civil rights and capacities, and becomes, as it were, dead in law. Formerly it took place, also, where a man abjured the realm, or went into a monastery and became a monk, in which cases he became dead in law, and his estate fell to the next heir.

CIVIL LAW .- By this term, absolutely taken, is generally understood the civil or municipal law of the Roman empire, as comprised in the Institutes, the Code, and the Digest of the emperor Justinian, and the Novel constitutions of himself and some of his successors. Like the canon law, it has no force where it is repugnant to our common law, it has no lored where it is pengiamin to our common law, and the courts of the latter will prohibit any excess of jurisdiction, if attempted by any tribunal dealing with the civil law. (See Canon Law.) Crvit. List, was formerly applied to the list of all the expenses of the civil government of the

of all the expenses of the civil government of the country. Down to the time of the Restoration, the whole expenses of the government, civil and military, were included in one list; but a distinction was then made between the military and the civil expenses of the government. During the reign of William III. the amount of the civil list averaged about £680,000 annually. Under this head were included the expenses of the royal household, of the privy purse, maintenance of the royal palaces, salaries of the lord chancellor, judges, officers of state and ambassadors at foreign courts, incomes to the members of the royal family, secret money, pensions, &c. In succeeding reigns the amount of the civil list was much increased, until, by I Will, IV. c. 25, it was confined to expenses proper for the maintenance of the royal household, and the sum of £510,000 granted to his majesty exclusively for the maintenance of the royal household, and the sum of £510,000 granted to his majesty exclusively many curves the splains and expresses of the for the privy purse, the salaries and expenses of the household, secret-service money, and pensions. The civil list is fixed in the first session of parliament after the accession of the sovereign, and is understood to be granted for the whole period of his reign. Her Majesty's civil list was settled, as in preceding roigns, on her accession to the throne, by 1 & 2 Vict. c. 2. In terms of that act she surrendered the hereditary revenues of the crown for life, in consideration of an annual sum of £385,000, for the support of her majesty's household and the honour and dignity of the crown. The application of this sum is intrusted to the lords of the treasury, and it is apportioned among the several branches as follows:—Privy purse, £60,000; retired allowances, salaries, and wages, £131,260; expenses of household, £172,500; royal bounty, alms, and special services, £13,200; beaving an unappropriated surplus of £8,040; but at the end of each year the lords of the

## Civil Service

treasury are authorized to direct that the savi treasury are authorized to direct that the navings any one of these classes may be applied in aid of a charges under any of the others. In addition to a above sum, £1,200 is granted to her Majesty for as and every succeeding year of her reign, cumulative for the payment of pensions to "persons who have a claims on the royal beneficence, or who, by the performance duties to the public, or by their useful discoveries, science and attainments in literature and the arts, his persisted the gracious consideration of their security. merited the gracious consideration of their sovereign and the gratitude of their country." It is further provided, that if in any one year the civil-list charge should exceed the total sum of £400,000, then an a count of the particulars of the excess shall be laid before parliament within thirty days.

CIVIL SERVICE, is applied to that department of the government service which is neither naval nor military. In it are included the post-office, customs, inland rewar-office, Admiralty, Board of Trade, courts of law, diplomatic corps, &c. The following are the amounts voted for the several branches of the civil service for the year 1869-70.

I. Public Works and Buildings II. Salaries and Expenses of Public De	£1,228,806
II. Salaries and Expenses of Public De partments	1.733.681
III. Law and Justice	3,712,426
IV. Education, Science, and Art	1,628,170
V. Colonial and Consular Services	
VI. Superannuations and Charities	
VII. Special and temporary objects	
Civil contingencies	131,174
Total	£9 530 158

The number of persons employed in the civil service in any capacity (excluding law courts and law offices) was, by the last return, as follows:—

	15 11
I. Heads of departments (political, 34; non-	190
II. Sub-heads of departments and heads of branches	1,469
Clerks (established, 13,768; temporary, 389)	14,157
III. Professional officers (superior, 1,922; m- ferior, 1,921)	3,843
1V. Inferior officers (in-door, 2,259; out-door, 36,566)	38,825
\ Artisans and labourers	20,010
VI. Persons not wholly employed, women, &c.	14,941
Total	103.058

In the fixed civil service there are two kinds of offices: there are, first, what are called the staff, or special appointments, t. e., certain situations to which men are appointed at once, irrespective of any previous connection with the comine. are appointed at once, irrespective of any previous connection with the service. These are usually the highest offices, which rank, in point of dignity and emolument, next to the ministerial offices, but differ from them in being held permanently. Bistinct from staff appointments are what may be called graduated appointments, or those which are arranged in an ascending scale, so that one must enter at a particular ascending scale, so that one must enter at a particular stage, and pass through the lower in order to reach the higher. As a general rule, clerkships in all departments of the service are graduated appointments, one entering as a clerk of the lowest grade, with a salary of £80 or £90 a year, and gradually working his way upwards. There are, however, many other kinds of offices that are thus graduated, as in the post-office and custom-house. Of the salaries enjoyed by the different classes of officials the following is an approximation. Of those styled heads of departments the salaries may be said to range from £1,000 to £5,000, but the majority are under £2,500. The salaries of cecreaties and chief clerks range generally from £1,000 to taries and chief clerks range generally from £1,000 to £2,000. Sub-heads of departments, and heads of branches, have usually from £500 to £1,500 a year, varying with the nature of their occupations. The varying with the nature of their occupations. The great body of clerks in the public service may be distributed into four classes, those in the lowest having

511

cataly of £80 or £30 s year, and those in the highest from £500 up to £700 or £800. Of the office-keepers, messengers, porters, artisans, labourers, &c., the salaries or wages may be said to range from £150 a year down to under £1 a week. The chief doorkeepers and messengers of the houses of parliament, however, have salaries ranging from £150 to £400, or more, per annum. Formerly appointments to the civil service were obtained chiefly by favour, and frequent complaints were made as to the inefficiency of the servants. In 1854 a commission was appointed, which reported most unfavourably on the existing system of appointments; and hence, by an order of souncil, dated £1st May, 1855, it was ordained that commissioners be appointed to examine young men proposed for any of the junior situations in the civil establishments, and grant certificates to such as they shall find duly qualified, having previously ascertained that they are within the prescribed age, free from physical defect or disease, and of good moral character. After receiving his certificate, the candidate enters upon a six months' probation, during which his conduct and a six months' probation, during which his conduct and capacity for business are tested, and, if found satis-There are two kinds of examinations,—pass and competitive. In the pass examinations,—pass and competitive. In the pass examinations there are no marks assigned, the candidates being reported upon by epithets as to the nature of their work. In competitive examinations marks are employed. (See Examination.) The ages for admission are generally fixed at between 18 and 25. In 1860 there were 2,631 persons nominated for examination; and of these, 317 were rejected in the non-competitive examinations; 103 were ineligible on account of age or other causes. Of the competitive account of age or other causes. Of the competitive meminations, 603 only were examined; and of these, 407 were unsuccessful; 319 were not considered to have been qualified, if they had possessed absolute nominations. On retiring from the civil service, the servant receives a pension for the rest of his life, proportioned to the period of his service and the amount

of his salary.

OIVIL WAR, a war between the inhabitants of the same state, or the citizens of the same city,—one of the greatest misfortunes that can befall a nation. The Wars of the Roses, the war between the Parliament and Charles I., in this country, and the present struggle between the Northern and Southern states of America, are the most notable civil wars since ancient

times.

CIVILIAN, sip-il-yan (Lat. civis, a citizen), a popular term signifying a person who is neither clerical, military, nor naval by profession. In Law, a civilian is a person who has studied the law and principles by which civic rights may be vindicated honourably, either in general society or in the special state to which he belongs. The civil law of nncient Rome was much studied in all the states of Europe in former times, and greatly influenced the formation of many musicinal systems. Those who devoted much study municipal systems. Those who devoted much study to the nature of these laws were called cicilians; and on account of the more severe character of the studies required, the term gradually was applied to the pro-fessor or doctor, as distinguished from the practitioner of laws. At present, in this country, the term is still applied to a student or teacher of Roman civil law.

applied to a student or teacher of noman civil new.
CEVILIZATION, six-id-zai-zai-zain (lat. circ, a citizen),
is one of those terms in common use which it is difficult
accurately to define in words. It is derived from the
Latin word sivis, a citizen, probably from those who live
in citize being more civilized than those who inhabit country parts, or from the living in cities being one of the great characteristics of civilized life. "Whatever." asys J. S. Mill, " be the characteristics of what we call savage life, the contrary of these, or the qualities which assage life, the contrary of these, or the qualities which society puts on as it throws off these, constitute civilization. According to Guizot, the fundamental idea of civilization is progress or development,—the perfecting of civil life or of society, properly so called; but-comprising, also, the development of the individual internal life, the development of man himself, of his fagulities, his centiments, his ideas. Hence civilization subsists on two conditions, and manifests itself by

of advancement from the savage state to that higher and more perfect condition which both reason and revelation lead us to believe to be the ultimate deatiny of the human race. The history of civilization is the history of this progress, either in nations or in the race. It is a subject of the utmost importance, sud, as yet, little has been done towards its elucidation. According to M. Guizot, the history of civilization may be considered under the different spacers and treated be considered under two different aspects, and treated in two different ways. The historian may either place himself in the heart of the human mind for a given period, a series of ages, or among a determinate people, studying, describing, and relating all the events, transformations, and revolutions which had been accomplished in the internal man, and he would then have a history of civilization amongst the people and in the period he had selected; or, instead of penetrating the internal man, he may take his stand in the midst of the world, and, instead of describing the vicesitudes of the ideas, the sentiments of the individual being, he may describe external facts, the events and changes of the social life. These two modes of treating civilization are intimately connected together; they are the reflection and image of each other. As we view the history of the human race from the earliest times to the present, the progress of civilization is very marked. It is not, indeed, in one undeviating straight line, nor is its course constant and uninterrupted. Sometimes it has the appearance of being at a stand-still, or even to be going backward; but this is only for a brief space, snatching, as it were, a breathing-time, in order with the greater vigour to again pursue its onward course. Very remarkable changes, too, have taken place among those nations that from time to time have occupied the foremost place in history. Nation after nation has, for a time, taken up the beacon-light, running with it onward for a time, and, when it begins to falter or fail, succeeded, as it were, by another of stronger and fresher energies. Many nations that once occupied the ran in civilization have passed away, and live only in name. These are not confined to one district of country, nor even to one continent; at one time in Africa, at another in Asia, now in Europe, and anon it may be in America or Australia (when the New Zealander shall come over and contemplate the ruins of Saint Paul's). It seems as if, in each succeeding nation that arose, and under each clime, there were cer-tain elements that favoured its growth for a time, and at a particular state of its progress; and that, when these were exhausted, the people that furnished them perished as useless. Or does it not rather seem, in most cases, that the very people that were ministering to the advance of civilization in one direction were, in another, imbibing the very poison of which it was purifying itself, and thus accomplishing their own destruction? In it not thus that the very refinements of civilized life have been the bane of so many? What, then, are the causes at work in producing these changes,
—in effecting this progress? This is the most important in connection with civilization, and this ought to be the great aim of its history. They are evidently of a twofold character,—internally in the race and externally in nature. The external or physical agents by which the human race are most powerfully infin-enced are, according to Mr. Buckle, climate, food, soil, and the general aspect of nature. But that these external agents are not all, or, perhaps, even the main agents at work, is evident from the fact that we find nations living under the like external circumstances, and yet in very different states of civilization. The external circumstances in Greece and Rome were the same This is one of the great errors into which Mr. Buckle has fallen. He overlooks the importance of the fact connected with the difference of race. Much as there is of error and loose reasoning in Mr. Buckle's book, it is undoubtedly a work of great ability, and is one of the first attempts made to systematize the history of civilization. It is deeply to be regretted that the premature death of the author has left us only a fragment of the work. Mr. Buckle contends that it can be shown by positive epidence that human actions are two symptoms,—the development of social activity and governed by fixed laws, and that "when we perform an that of individual activity,—the progress of society and action, we perform it in consequence of some motives the progress of humanity. Civilisation denotes a state or motives; that these motives are the results of some

Chadonia

antesedents; and that, therefore, if we were sequented with the whole of the antecedents, and with all the laws of their movements, we could with uncerfug certhe mind over external agents; and the time distrements.

The measure of civilization in his view, is the "triumph of the mind over external agents;" and that in Europe the tendency has been in man to triumph over nature; the tendency has been in man to triumph over man. The out of Europe, in nature to triumph over man. The only possible way of arriving at a scientific knowledge upon these subjects lies, he thinks, in studying the mental phenomena, not simply as they appear in the mind of the individual observer, but as they appear in the actions of mankind at large." While admitting that human actions are governed by fixed laws; yet it is doubtful how far the limited faculties of man will admit of his ever heing able to arrive at any satisfacadmit of his ever being able to arrive at any satisfac-tory knowledge of them. Whether a science of human action be possible is a question which Mr. Buckle has failed to solve. The circumstances "which influence the condition and progress of society are innumerable, and perpetually changing; and though they all change in obedience to causes, and therefore to laws, the in obsdience to causes, and therefore to laws, the multitude of causes is so great as to defy our limited powers of calculation."—(Mill's Logic.) The four leading propositions which Mr. Buckle regards as the bases of the history of civilization, and holds to be the most essential for the right understanding of history, are—"1. That the progress of mankind depends on the success with which the laws of phenomena are investigated, and on the extent to which a knowledge of these laws is diffused; 2, that hefore such investigation can begin a spirit of seambefore such investigation can begin, a spirit of scepbefore such investigation can begin, a spirit of seep-ticism must arise, which, at first aiding the investi-gation, is alterwards aided by it; 3, that the dis-coveries thus made increase the influence of intel-lectual truths, and diminish relatively, not absolutely, the influence of moral truths,—moral truths being more stationary than intellectual truths, and receiving fewer additions; 4. that the great enemy of this move-ment, and therefore the great enemy of civilization, is the protective spirit; by which I mean the notion that society cannot prosper unless the affairs of life are watched over and protected at every turn by the State and the Church; the State teaching men what they are to do, and the Church teaching them what they are to believe."

CLADONIA, klu-do'-ne-d, in Bot., a gen. of Lichens. C. rangiferina is the reindeer moss, so termed from constituting the principal food of the reindeer. C. pyxidata is commonly termed cup-moss; it has been em-

ployed as a remedy in hooping-cough.

CLAIM IN CHANCERT, klaim, is a proceeding, in certain cases, by which equitable relief may be obtained without special leave of the court, or filing a bill of complaint. It is lodged in the record and writ or compliant. 15 is louged in the record and write clerks office, on which the court takes cognizance of the matter. The cases in which proceedings by claim may be instituted are,—1. Where the plaintiff is, or claims to be, a creditor seeking payment out of a deceased person's personal estate. 2. A legatee under a will seeking payment out of the personal seast. a will seeking payment out of the personal assets. 3. A residuary legatee seeking an account of the residue, and payment or appropriation of his share. 4. A person entitled to the personal estate of an intestate seeking an account of such estate, and payment of his share thereof. 5. An executor or administrator of a deceased person seeking to have the personal estate administered under the directions of the court. 6. A legal or equitable mortgagee, or person having a lien as security for a debt, seeking foreclosure or sale, or otherwise to enforce his security. 7. A person entitled to redeem in the last-mentioned cases. 8. A person entitled to a specific performance of an agreement for sale or purchase of any property. 9. A person entitled to an account of purtnership transactions dissolved or expired. 10. A person entitled to an equitable estate or interest, and seeking to use the name of his trustee in prosecuting an action for his sole benefit. 11. A person estatled to have a new trustee appointed in a ase where there is no power in the instrument creating the trusts to appoint new trustees, or where the power cannot be exercised, and seeking to appoint a new trusteo.

CLAIRFOYANCE. (See SOMNAMEULISM.) CLAMP. (See JOINEBY.)

Clarichord

OLAF, klin (Gael, clann, children or descenden common successor), it is body of men united Sensets by common ancestory, or some other tree. It is an particularly applied to those associations or driber the Scotch Highlands which are united together one common name, and are supposed to be descess from a common ancestor, of whom the chief is the life. from a common ancessor, or whom the enter is the interest representative. This system of clauship was essentially patriarchal, and similar to that which still exists among the nomadic tribes of the East. It was thus entirely different from the feudal system formerly prevailing in Europe; and hence it sometimes happened that the chiefship and the estates occupied by a clan were centesting and the estates occupied by a olar were vested in different persons. The Highland claim formerly enjoyed a bad fame among the lowland Scots for their predatory habits. "Being divided," says Camden, "into families, which they call claims, what with plundering and murdering, they commit such barbarous outrages, that their cavage orucity habs made the law necessary which enacts that if one of says, when bath acquirited a treester the vest shell exacts. clan hath committed a trespace, the rest shall repair the damage, or whoever of them is taken shall suffer death

CLANDESTINE, klan-des'-tin (Lat. clandestinus), in applied to anything done secretly, without the know-ledge of the parties interested, or without the proper-solemnities. Hence a marriage is said to be claudestine when performed without the publication of banns and the knowledge of parents or guardians. (See

MARBIAGE.)
CLAQUE, klak (Fr. claquer, to clap the hands), is the name given to the means by which public perform-ances are secured a favourable reception. In Paris, one M. Santon established, in 1820, an office for the assurance of dramatic success, and was thus the origin-ator of the so-called Parisian claque. Sometimes when the success of a piece is very doubtful, as many as from 300 to 500 claqueurs are sent to applaud it. They are even frequently instructed in the details of the piece, and shown beforehard what parts they are to appland. They have also particular parts assigned to them: the laughers (rieurs) must laugh at every joke, the weepers (pleureurs) weep at all the moving passages, the chatquillers seek to keep their neighbours in good humour, while the bisseurs encore particular parts of the performance.

CLARE COLLEGE, CAMBRIDGE, klair, was founded by Lady Elizabeth, sister and co-heir of Gilbert, earl of Clare, in 1326. At present it consists of a master, eight senior and nine junior fellows, besides scholars, students, and foundation-servants. The seventeen fellowand toundation-servains. The seventies remove ships are perfectly open to all persons who are bachelors of arts, or of a higher degree, without any limitation as to age or length of standing in the university. There are eight scholarships of £00, eight of £40, and eight of £20 per annum at this college. The number of undergraduates in 1870 was 70; of members on the boards, 285.

CLARE, NUNS OF THE ORDER OF ST., were instituted by St. Clare at Assisi, in Italy, about 1212, and subsequently confirmed by Popes Innocent III. and Hororius III. They observed the rule of St. Francis, and were habits of the same colour with those of the Francisco III. ciscan friars. Hence they were called Minoresses, and their house without Aldgate, London, where they first settled when brought over into England, about 1293, the Minories. They had only three houses in England

besides this one.

CLABENDON, THE CONSTITUTIONS OF, klär-en-don, in English Hists, were certain ordinances made at a general council of the nobility and prelates, assembled by Henry II. at Clarendon, in Wiltshire, A.D. 1164. These enactments, sixteen in number, were designed to check the power of the pope and his dergy, and to limit the total exemption which they claimed from secular jurisdiction.

secular jurisdiction.

CLIET, klär-et (Fr. clairet, from clair, clear), a name used in England to denote the red wine of Medoc, and a term generally applied to the light red wines of France. Clairet, in France, signifies those wines which are red or rose-coloured; but the word, as used by us, and employed to describe every description of lightred wine, is unknown in France.

CLARICHORD, or CLAVICHORD, klin's-kord (Lat. clorus, clear; chorda, aestring), a keyed instrument.

resembling in form a spinet, now almost extinct. The strings are supported by five bridges, and covered with pieces of cloth, which soften and, at the same time, so deaden the tone, as to prevent its being heard at any countdershle distance. On this account, it was formerly much used by nuns, as they could practise it without disturbing the silence of the dormitory.

CLARION, kile-uses (Fr. claivon, from Lat. clarus, clear), a kind of telement whose tube is narrower, and tone more scute, than the common trumpet. It is said that the clarion now in use amone the Moors served

that the clarion new in use among the Moors served anciently for a treble to several trumpets, which sounded tenor and bass.

Charloner, blar co-net' (Fr. clarinette), a musi-i wind instrument, invented about the close of the 17th century by a German named Denner, and first introduced into Great Britain about 1779. It consists of four parts; viz. the mouth-piece (on which a flat reed is fastened), the upper joint, the middle piece, and the bell, or bettom piece; and has thirteen holes, the of which are stopped by keys. To these keys the instrument is indebted for its chief use, as, before their invention, it could not be employed in concert, as at present. Although chiefly used in concerted music, in which its charming effects are too well known to need encomium, its fulness and sweetness of tone as a solo instrument is extremely pleasing. This instru-ment bears a nearer resemblance to the female voice than any other extant. Some great improvements were made in wind instruments about eleven years since by M. Boehm, who brought the acoustical proportion of the subes and finger-holes into correct num-bers and measurement, by which means flutes, oboes, clarionets, &c., may be theoretically constructed. He also invented a mechanism for the keys, which gives much greater facility and precision to the execution.

CLASS, kias (Lat. ciassis), in Bot., a group of orders possessing some important structural characters in common. In the system adopted throughout this work, we have the classes Monocotyledones, Dicotyleidones, and Acotyledones, which present certain distinc-tive characters in their embryos, from which they derive their names; and they present, morcover, other important anatomical differences.

Classic, klds-sik, is a term derived from the Latin word classici, the name given to the first, or highest class of Roman citizens. Hence it came to be applied figuratively to writers of the highest rank, and this is the sense in which it is commonly used in the present day. The highest and purest class of writers in any language are termed the classics; but, in a more limited sense, the name is given to the best writers of ancient Greece and Rome. In another sense, and as opposed to modern, it is applied to the productions of

ancient Greece and Rome.

CLASSIFICATION, klüs-sij-s-kai'-shun (Lat. classis, a slass), in a general sense denotes the arrangement of a variety of objects into groups or classes, according to their resemblances or differences. It is from power of abstraction in the human mind,-the power of considering certain qualities or attributes of an object, apart from the rest, that classification is possible. We assurtment or arrangement can be formed among things not perfectly alike but by losing sight of their individual or lesser peculiarities, and limiting the attention to those which they have in common. properties that may be adopted as the basis of classification are very various, as may be seen in the nume-rous botanical, geological, and other systems. When the properties on which the classification is based are arbitrarily selected, the system is said to be artificial; when they lie in the essential nature of the objects themselves, it is natural. "The ends of scientific (or matural) plassification are best answered when the objusts are formed into groups, respecting which a greater number of general propositions can be made, and those propositions more important than could be made respecting any other groups into which the same things bould be distributed. The properties, therefore, ac-cording to which objects are classified, should, if poscorang to when objects are classified, should, if pos-nible, be those which are causes of many other proper-ties, or, at any rate, which are sure marks of them. Causes are preferable, both as being the surest and most direct of marks, and as being themselves the preparties on which it is of myst use that our attention

should be strongly fixed. But the property which is the cause of the chief peculiarities of a class, is, unfortunately, seldom fitted to serve also as the diagnostic of the class. Instead of the cause, we must generally select some of its more prominent effects, which may serve as murks of the other effects and of the car

"The end of classification as an instrument for the investigation of nature, is to make us think of these objects together which have the greatest number of important common properties, and which, therefore, we have oftenest occasion, in the source of our inductions, for taking into joint consideration. ideas of objects are thus brought into the order most

conducive to the successful prosecution of inductive inquiries generally."—J. 8. Mill's Logic.
CLAVICIE, or COLLAR-BONE, klav's-kl (Lat. classicala, from clavis, a key), in Anat, is the bone which extends horizontally from the sternum to the scapalis, and serves to keep the shoulders apart, that the arm may enjoy a freer and wider range of motion. It takes its name from its resemblance to the ancient Roman key. Its sternal end is thick, strong, and expanded, while the acromial end is broad and flattened, and presents an oblong surface, in order to articulate with the acromion process of the scupula.

CLAY, kin [Say along] and it is curved somewhat in the form of an italic

CLAY, klai (Sax. clag) .- Clay is formed from the disintegration of felspathic rocks by the combined action of the air and water. It necessarily varies in its composition, but its fundamental constituent, according to the researches of Brogniart, Malaguti, and others, may be represented by the formula AZ<sub>2</sub>O<sub>3</sub>, 2Si O<sub>3</sub>+2aq. This is as nearly as possible the composition of the fine fire-clay of the Staffordshire coal-measures. Ordinary clay contains, in addition, small portions of undecomposed rock, potash, oxide of iron, lime, and magnesia, the character of the clay being much modi-fied by the preponderance of one or other of these ingredients. One of the great characteristics of clay in its hydrated condition is its plasticity, and its carability of being made hard by heat,—properties which render the different kinds of this substance available for various fictile purposes. The purest kind able for various fictile purposes. The purest kind of clay is kaolin, or cluna-clay, which is formed by the disintegration of felspathic rocks. This species was originally found in China; but a similar description is originally found in China; but a smaller description is obtained from deposits near St. Austle, in Cornwall, and at St. Yrieix, near Limoges, in France. Kaolin is nearly pure silicate of alumina. (See Poncelative Manusacruse.)—Pipe clay is a white clay nearly free from iron, and found in large quantities in the sistend of Purbeck.—Common potter's clay contains a considerable amount of iron. The blue clay of Devention and Devention and Devention is a considerable amount of iron. shire and Dorsetshire is much valued, being very plastic, and yielding a very white paste when burni. The coarser carieties, which contain a large proportion of sand, are used for making brown stone-ware. - Brick clay contains varying proportious of iron; hence different counties build houses of different colours. clay of the midland counties contains large quantities of iron, and the bricks made from it are of a bright red thus, while London bricks are yellow or brown, from deficiency of colouring material. When the proportion of iron is very much increased, we get the different coloured celtres.—Mar! is clay containing a notable proportion of carbonate of lime. The colours known as er and sienna are clays coloured by the peroxides of iron and mangaines.—Fuller securit is a clay of a peculiar kind, which, when dried, possesses the property of absorbing grease from woollen fabrics, and is employed for that purpose. It contains a small percentage of magnesia.

CHATLAGE OF MARDESIS.

CLAY LORSTONE. (See STENCHNAS.)

CLEAVAGE, kleev'-oj (Sax. cleojan, to split), in
CTSTALA, a term applied to the property possessed by
crystals of separating into natural layers. (See CENS-TALLOGRAPHY.)

CLEAVERS. (See GALIUM.)
CLEF, klef (Fr. clef, Lat. clavis, a key), in Mus., a certain character placed at the commencement of the several stayes of a composition to determine the local names of the notes, and the sounds which they repre-sent. There are three kinds of clefs now in use; vis-the F, or bass clef; the C, or tenor clef; and the G,

### Clematidese

or troble clef. These, by the different situations in which they are placed, furnish us with a means of expressing all the notes within the usual compass of execution, either vocal or instrumental, without a confused addition of legar-lines either above or below the

CLEMATICES. Elem-a-til-de-s (Gr. klema, a tendril), in Bot., a tribe of plants in the nat. ord. Ranunculaces, distinguished by the union of the following structural points:—Calyx valvate or induplicate; fruit consisting of a number of achienia; seed pendulous. The typical genus of the tribe is Clematis, which includes several issuiffed chimbers commonly cultivated in our gardens; also one indigenous species, C. vitalba, usually called traveller's joy

CLEMENTINA, OF CLEMENTINE HOMILIES, klem-en-dr-ma, in Eccl. Hist., are nineteen homilies of a Judaising tendency, faisely attributed to St. Clement The generally received opinion is, that they were composed by an Ebionite, towards the end of the 2nd contairy

CLEMENTINES, OF THE CLEMENTINE CONSTITUTIONS, klemen-feens, is the name given to a collection of decretals of Pope Clement V., published by his successor, John XXII., in 1317, and forming part of the canon

CLERESTORY, kleer'-stor-s, in Arch., this name is applied to the windows that are pierced in the upper part or the side-walls of the nave of a cathedral or church, that rise above the arches which separate the nave from the side-aisles.

CLERGY, kler'-je (Lut. clericus, Gr. klerikos), is a term applied collectively to the whole body of ecclesiastics, in contradistinction to the laity. The distinction of Christians into clergy and laity is as old as the time of the apostles, and was derived from the Jewish economy. As soon as the Christian church began to appeal and as the contradisting to the contradiction of the cont spread, and sufficient numbers were converted to form themselves into a regular society, then certain eccle-sisatical officers were appointed among them as teachers The clergy originally consisted only of bishops, priests, and deacons; but in the 3rd century many inferior orders were appointed as subservient to the office of deacon; such as subdeacons, acolytes, readers, &c. At first, probably, the clergy were not entirely relieved from the ordinary duties of life, so that they might devote themselves exclusively to their ascred office; yet it must have necessarily been nearly so, and it is certain that they were nominated to their offices by certain peculiar forms. The privileges and immunities enjoyed by the clergy of the early church were considerable. In some cases they were exempt from the cognizance of secular courts, from certain taxes and certain kinds of obligation to which others were liable, and were excused from the burden of civil offices. Whenever they travelled, upon necessary occasions, they were to be entertained by their brethren of the clergy in all places, out of the public revenues of the church. If any controversies happened among them, they freely consented to have them determined by their hishops and councils, without having recourse to the secular magistrates. In all accusations against the clergy, especially against bishops, the character of the witnesses was inquired into before the testimony was admitted; nor would they receive the evidence of a heretic against a clergyman. The crimes involving punishment were simony, heresy, apostsey, murder, immorality, neglect of duty, &c.; and the punishments were various. Corporesi castigation and imprisonment were sometimes resorted to; degradation, suspension, deprivation, and excommunication were the other modes usually had recourse to, according to the heinousness of the offence. The laws regarding the duties of the various classes of clergy were definite and stringent. No clergyman was allowed to relinquish his station without permission; and he could not remove from one diocese to another without the consent and letters dismissory from his own bishop. In some osses they sould resign, and a retiring allowance was sometime s granted to such. Residence in their r specific enter was obligatory, and no one could hold office in two dioneses. Severe laws were enacted against wandering clergy (vacantivi), or such as, having deserted their own church, would fix in no other, but went rowing from place to place. There were also laws

# Clerk

prohibiting them from following any secular employment which might divert them too much from their price fruites. They were likewise forbidden to frequent fairs or markets, to eat and drink in taverus, or is attend public theatres. No special derical dress appears to have been in use before the 6th century. The clergy of the Church of Rome are distinguished into regular and secular. The regular clergy consists of those monks or religious persons who have taken upon them holy orders and perform the officer of the religious. them holy orders, and perform the offices of the pr hood in their respective monasteries. The secular clergy are those who are not of any religious order, and have the eare and direction of parishes. The Pro-testant olergy are all secular. In England, the berm clergy, in its ordinary acceptation, comprehends are bishops, bishops, deans and chapters, archdes rural deans, parsons (either rectors or vicers), and curates; to which may be added parish clerks, who formerly were, and yet sometimes are, in holy orders. Most of the privileges and immunities which the clerks enjoyed in England were taken from them at the time of the Reformation. Among those which they still possess are exemption from serving on a jury, or appearing at a court-leet or view of frankpiedge. They cannot be compelled to serve the office of bailiff, reserve constable, or the like; neither can they be pressed as serve during the wars. They are privileged from arrest in civil cases in going to, during, or returning from the celebration of divine service. Clergymen are disqualified from sitting in the House of Commons, nor can they engage in any kind of trade. Neither can a clergyman farm lands to the extent of more than eighty acres without a written permission from the bishop of the diocese, such permission specifying the number of years for which it is granted, and in no case exceeding seven. Clergymen are, by the ecclesiastical law, liable to be punished and corrected for loose, imlaw, name to be punnished and corrected for icose, un-moral, and profane conduct, for irreligious language, for irregularity in discharge of duty, or for presaling and maintaining doctrines contrary to the articles of the creed which they profess. For such they may be called to account by their ecclesiastical superior, by whom they may, if the charges are proved against them, be punished by admonition, suspension, degra-dation or doministic as the case way receive. dation, or deprivation, as the case may require

CLERGY, BENEFIT OF. (See BENEFIT OF CLERGY.) CLERK, klerk (Lat. clericus), was a term originally applied only to clergymen, being, in fact, a contraction of the Latin word clericus. As learning was at one time almost entirely confined to the clergy, the word naturally came to be synonymous with a learned man, or one who could write. Hence we have the double meaning of the term,—a clergyman, and a scribe, or one whose principal business is writing. In the former sense it is now seldom used except in formal documents; but from it has come a secondary meaning, in which it is applied to certain laymen appointed to conduct or lend the responses of the congregation. These were originally real clerks, i. s. clergymen, generally in minor orders, who assisted the officiating priest, Parish clerks, after being duly chosen and appointed. are usually licensed by the ordinary. By a recent enactment, persons in holy orders may be appointed to this office Until recently there were a large number of clerkships, connected principally with the courts of law, having ancient and quaint names, derived from of law, having ancient and quaint names, derived from some incident of their origin; as, clerk of the banaper, clerk of the petty bag, clerk of the pells, clerk of the pipe. Most of these were abolished by acts of paritisment in 1832 and 1837. The proceedings of the two houses of parliament, of the various courts of justice, and of the ministerial departments, are generally drawn up and recorded by clerks.—The Clerk of the Parliaments is the chief ministerial officer of the House of Lords, he and his assistant washe minutes of the of Lords; he and his assistants make minutes of the proceedings of the bouse, record its votes, resolutious, orders, and divisions, issue directions consequent upon its orders; prepare the journals, and superintend and verify the preparation and distribution of the printed documents issued by the house.—The Clerk of the House of Commons is the chief officer of that house, but now model he is desired it he marked. but nominally he is deputy of the clerk of the parliaments. He helds office for life under letters patents from the crown. He has the general charge of the official business of the house, assists and advises the

# Cleveland Ironstone

speaker in matters relating to the rules and practice of the house, and signs all orders and all bills which pass the Commons; he has the custody of all records and other documents of the knuse, and a required to take notes of all orders and proceedings, and to record the votes. The Christ of the Cross is Chancery is an officer of the crown in attendance upon the lord chancel for in maritimenest. We need to the record and success all write of lor in parliament. He makes out and issues all write of summons to peers, write for the attendance of judges, communicates to summon and proroque parlament, and depass bills. He also makes out and issues all write for the elaction of members of the House of Commons and the assection of members of the House of Commons and England and Southand, receives and has the custody of all returns to parliament for the United Kingdom, and has also the custody of all poll-books taken at elections. He also makes out all warrants, commissions, appointments, or other instruments that pass

CLEVELAND IRONSTONE (See IRON.)
CLEVELAND IRONSTONE (See IRON.)
CLIEBT, & Wo employs an attorney, solution, or proceeding, who employs an attorney, solution, or proceeding, who employs an attorney, solution, or proctor to sonduct his case in a court. Among the Romans as chent was a onizen who put himself under the protection of some great man, who, in respect of that rela-tion, was called patron He assisted his chent with his protection, interest, and goods, and the client gave his octs for his patron when he sought any office for him self or friends The 11ght of patronage was appointed by Romulus, to unite the rich and poor together in such a manner as that one might live without contempt, and the other without envi but the condition of a client, in course of time, became little else than a modern slavery. (See Attobney)
Chimacteric, kli mak-ter-ik (Lat climactericus un-

was, from climax, a ladder or steps), denotes a critical year or period in a man's life, wherein, according to astrologers, there is some notal le alteration to hapmen in the body, and the person will be exp and to give t danger of death. The idea of climateries is very ancient. According to some, every seventh year of a man's life as a climatorie of the contraction. man's life is a climacteric year, certain important changes then taking place in the lody. The ages of 63 and 61 are regarded as the grand climateries, the changes being then greater, and the danger attending these periods much increased. Others allow the term climarteric only to the product of 7 multiplied by odd numbers, as 5, 5, 7, 9, & Some, again, consider every ninth year a climacteric

CLIMATE, klv'-mut, 18 derived from the Greek word CLEARTY, kit-said, is delived from the Greek word kana, signifying inclination, but which was also applied to certain zones on the earth surface, from their supposed inclination to the pile. The space between the equator and the poles was, by the anothin geographers, divided into thirty such zones or inclinations. mata). The first twenty four, counting from the equator, were called half hour climates, because they were determined by the length of the longest day every half-hour, in its length from the equator, denoting a new climate. The last six were called month climates, because, being within the arctic circle, each was marked by an additional month of continuous sunshine alimates of ancient geographers, therefore, served 's esame purpose as our parallels of latitude. In its present and most general acceptation, the word climate may he said to include all those atmospheric conditions and changes that sensibly affect our organs, buch as heat, moiature, winds, electricity, &c The principal elements, however, that go to constitute climate are heat ments, however, that go to constitute climate are heat and monture, the latter being depend at upon the former. Heat is communicated to the atmosphere in three ways,—(1) By the direct rays of the sun, (2) three ways,—(1) By the direct rays of the sun, (2 by the reverberation of these rays from the ground and (3) by contact with the ground. The sun being that the great source of heat, it follows that, as a general rule, the temperature of a place would depend upon its latitude, or distance from the squastor, and that all places in the same latitude would anjoy the same kind of clumate. Were the would enjoy the same kind of climate Were the springs of the earth composed of a homograpous finid mass, or of strats of rock perfectly alike medicut, density, and smoothness, then this would actually be able ease; for all places in the same latitude would receive the solar rays at the same angle, and having the same capacity for absorbing and radiating heaf, would possess exactly the same climate 516

# Climate

There are, however, various diretimateness that tend to modify the climate of a country; as height above the level of the sea, inclimation of the surface, proximity or distance from the sea, the position and direction of mountain-chains, nature of the soil, state of cultivation, prevalence of particular winds. Rievation above the sea-level is one of the most important modifying circumstances, the air becoming gradually celler as we ascent; so that even in the tornal sone the summits of very high mountains are covered with perpetual snow. The nower of the suir rays in imparting heat or very high mountains are covered with perpetual snow. The power of the sun's rays in imparing least to the earth depending upon the angle at which they strike the surface, it follows that the inclination or slope of a country has an important influence upon its climate. Hence in the Alps of the Valus, for instance, on the one side may be seen the vine in lituurisant growth, whilst the other is thick-ribbed with ice. The occan is a very important element in determining the nature of a climate. Islands and districts near the sea uniformly enjoys milder and more uniform climate, than inland regions in the same latitude. In summer the sea is not so muc heated by the sun's rays as the land, and hence cooling sea-breezes temper the warmth of that season, while in winter the cold is miligited in consequence of the water retaining its heat longer than the land. Thus Dublin, though 4° in the next when I Widdlings has nearly the activities. "arther north than Hedelberg, has nearly the same mean mount temperature whilstis winters are almost 6° warmer and its summer nearly 5° cooler Mountains affect a climate in various ways, by influencing the direction of currents and by directing and condensing the appears in the atmos the supports in the atmos . The nature of the scil and the state of cultivary contrate materially upon Different kinds of so clima different powers chine principle and a region of "shating and absorbing in , and a region shrouded in forest, or covered with awamps and marshes, will have a different temp rature with a cleared and drained Maishta, ly evap ration, deprise the surface of much of its heat, and torests, by intercepting the sun ariys and by the increased exhalant sur faces exposed to the an, unfountedly after the temperature. Hence in hot climates forests tend to cool the an and in friend regions to present the loss of the carth sheat by chiling blasts. The prevalence of particular winds also influences the character of a current bringing water of a higher or a lower tempesture than that of the surrounging sea. It will thus be seen that there are nun clous circumstances that tend to modify the climate of any particular place, and that more lines of littude afford but an imperfect indestion of the temperature. Hence goographers ind citim of the temperature. Hence goographers have had recours to their lines called softhermal (Orien root, eval, and the mor, heat), which are carried through all place i having the same mean annual temperature. These lines diverge more and more and more and more are more and more and more are more and more and more and more are supported to the contract of th from the parallels of latitude as they recede from the equator In the American confinert they descend mu n lower than in Fuice, and in the southern hemisphere the mean annual temperature is much lower than in the northern, on account of its having much less land But places having the same mean annual temperature may vet have very different cli-mates, for places having a moderate summer and winter may yet have the same mean annual temperature as others where the summer and winter are extreme, Hence secouse is had to other lines indicating the mean summer and winter temperature, the former being called southerals (Greek sion, equal, and there, summer, the latter sochmenals (Greek sion, error, and chemon, winter). The second great constitutes of chemon, winter). climate is moisture, which takes the forms of rain, vapour, fog, and dew These will be noticed under their respective heads. In the torrid zone there are but two seasons, the wet and the dry. The former is regarded as the winter, the latter as the summer of these regions, but they are in direct opposition to the astronomical seasons, as the rains follow the sun. In India, however, the rainy and dry seasons are not regulated by the position of the sun, but by the change of the monscons. In some districts there are two rainy and two dry seasons; and in others rain seldom or never falls, as in the great African desert of the Sahara. Only in the temperate zones can the year be properly said to be divided into four argains, ex-

hibiting the agreeable requirement of tiens and cold, the bengorate beats of entering the health the feet of the health the feet of white in Lindly open with the rapid that me of spring and attached, in the first score only two secons are known—a long and severe water, followed by a chort but firrid summer. This hard and abroupt transition is occasioned by the great length of the day in aumaner, when for a time the sun never sets, and by the total absence of that luminary in winter. It is to the varieties in the climate of different places what we are indebted for the great variety that exists that we are indebted for the great variety that exists in the regetable and animal kingdoms Every species of plant has certain climatic boundaries, some much notes the ded than others, within which alone it will somish Animals, too, have their climatic bounds The man alone is it given to subsist in any chimals. Even him, however, different climates affect very dif ferently,—some being favourable to health, others tending to disease The study, therefore of the effects of different climates upon different constitutions and in different diseases, forms an important branch of medicine Indeed, their are few disea is that miv not be influenced by climate, and hence the necessity to the physician of making himself acquainted with the stmospheric conditions of different localities

firmax, kle make (Gr. 1/1mar), is a plied to a figure in rhotoric in which the speaker accords as it were by a series of steps from ore iden to another, each being characterized by prester in cignits or importance than its reducesse. Suithful electron among of Julius Cusan. Vem vid sir: (Cosm. I saw, I conquered). "I say a e as lord kames "must have observe!" digitir electron num ber of thenghts or a stime to articlly engosed like net of th tights or a little is attitute to 1 year in team accurate and team is an imaking impression and deep is such disposition of mumbers in a period a termed a climax." The upposite of climax is anti-climax, or a descending from greater to less important

( I BING LOCOMOTIVES AND CARRIAGE alo the invention of Mr. Lell, the celebrate Lenguage in the track the passage of a railway over in. M. nt. the there are the passages of a raisea section in the constraint of the passages between I raise and Italian as let a practical success. Mr. Italian a paper which is real before the British Association, gave a engineered description of the construction of keep the congruence. and carriages on the centre rail system ! I wilk no on steep gradent and sharp curies as cin loyed on the Mout Cenis Summit Railway Mesers \ girlles and Enceson first concerned the use of the centre sail in the year 18 0 and proposed to apply it upon the inclines of the Manchest rand Liverpool Railway, but it was not put into peration it was not till like Brassey and Mr Lell built a centre call engine and laid down a length of one on that plan on the Cromford and High Peak Railway for experimental Cromord and right reas natural for experiments purposes, in 1865, that the sysfem was jut into practical operation. These experiments were made in order to assure the Italian givernment of the feasibility of laying down a line of railway upon a similar principle over one of the Alpine passes. The mean principle over one of the Alpine passes in the mean gradient of the first 24 miles of line, from 5t Michol to Lanelberg, 14 in 60, with a maximum gradient of 1 in 12 in the other 24 miles the mean 14 1 in 17, and over the whole length there are at intervals curves of two chains radius. The line rises to an curres of two chains radius. The line rises to an elevation of 7,000 teet and in places is exposed to elevation of 1,000 term and in places is exposed to anomadrites and availanches where it runs through sintably-strengthened galleries. The system of loco-ington adopted is that of a third or traction-rail, on which adhesion as attained by horizontal wheels, worked by the engine in conjunction with, or independently of, the ordinary driving wheels, which ad suit of the weight of the engine being reduced to a minimum, whilst the pressure upon the middle rail on be carried to any required amount, and gradients of 1 in 12 worked with as much certainty and safety as these of 1 in 160. The centre rail also furnishes the means of applying most powerful brakes for con-trolling the descent of the trains, and, moreover, senders at almost impossible for the train to leave the ruds. The requirements of the Italian government included three trains a day each way; the mail-train to perform the journey at an average rate of twelve mules an hour, racingling stoppages, the speed up the

CLIPTER, klip'-per (Ang.-Bax, one who runs fast),
a saling-vessel built expressly for speed. Compared
with ordinary ships, a clipper is longer and narrewer; the bows, which are generally hollowed below
the water-line, are extremely sharp, and the lines are
fined gradually towards the stem. Clippers owe their

prisin to th and the openin-eleppera. duns which sail beand America are among isting. Great improvements have s and dipper ships.

MORODOGY. th kied krusk er (Ang Bax), an agri-ment used for crushing and pressing the spend form it consists of a cylindical into many pieces, all strung upon one meces actually constitute a number of micht wheels, which are notched on the outer and the formed as to prevent the tearing up of and, which, when the common roller was the rolling a growing crop, was a serious

Chair Ashanac, or Runic Stair, klog, was a kind of skinshap or calendar formerly in use in England and Beandingwis, and was usually made of wood Dr Plot, in his History of Staffordshire (1886), describes one of these instruments, which, he says, is still in use among the meaner sort of people. "It is usually," he says, the meaner sort of people. "It is usually," he says,
"a square piace of wood, containing three months on
such of the four edges. The number of days in them
are expressed by notches the first day by a notch
with a judgestized motch. Over against many of the
notches sub placed, on the left hand, several marks or
symbols desicting the golden number or tycle of the
moors. The restreats are marked by symbols of the
several salata issuing from the notches." These which
had deep in Staffordshire had only the number of severes same securing from the notices. In see which he had been in Staffordshire had only the prime and immerable feasts upon them, whereas others of a more perfect kind, preserved in the cabinets of the curious, had likewise the Dominical letters. Of the frequently, was another the Dominion letters Of the frequent facer were two kinds,—a larger for family use, which simulty hong at one end of the mantel tree of the distance, and a smaller for carrying in the pocket Specimens are to be seen in the British Museum.

CLOSSEE, kloys for (Lat. claustium, an inclosed space), in a general sense, a monastery, either inhabited by monits or nuns, who are inclosed or shut up from the world. In a more restricted sense, the term is simplified to a covered passage running round the walls of certain portions of monasteries. It usually is found extending over three sides of a square or quadrangle, with the outer walls consisting of pillars and arches, and the roof frequently erched and ornamented with tracery. In the anotest monasteries the closetrs were used for several purposes. The monks held their lecters in the oblisters, and at certain hours of the day met there and conversed together

new many short (Set olath), a manufactured substance, consisting of wool, har, cotton flax, hemp, or other vegetable-diaments. It is formed by wearing or interlacing threads, and is used for making garments or cher devening, besides being useful in a great variety of forming; basides being useful in a great variety of forming; such as woollen cloth, hair cloth, co-ten cloth, hair efoth, ac. The term cloth, however, is generally simplered to distinguish woollen cloth from fabluce mander of they other material. (See Woollen Manu

COADUTOR, ke de juin (Lat con or sum, with, and a juior, an assistant) is a fellow-helper, or one engaged in the assistance of another. In confermatical Lauten

engaged in the assistance of another. In ecclemental matter, a conductor is one appointed to assist a lishop in his episcopal duties.

Loat, Tole (Sax cal or coll), is a mineral of vegetable origin. The hypotheses of the best authors are based upon the assumption that the occurracts of vegetable remains of all kinds in coal affords convenients. The enument geologist Six Cherles Legell, who has paid great attention to the phenomena of the conversion of coal, thus states his views.—"It appears conversion of coal, thus states his views —" It appears from the researches of Luebig and other emment chemists, that when wood and vegetable matter are buried mats, that when wood and vegetable matter are bursed in the earth exposed to mostime, and ignetiably or entirely excluded from the an, they decompose slowly and evolve carbonic and gas, thus parting with a pertino of them original oxygen. By this means they become gradually converted into lightly, or wood cost, which contains a larger portion of by drogen than wood does. A continuation of decomposition changes that lightle into common or butumnous coul, chiefly by the discharge of carburetted hydrogen, or the gas with which we illuminate our six sets and houses. According to Burchoff the unflammable cases which are slawer. which we illuminate our streets and houses. Ascording to Bischoff, the inflammable gases which are silverys escaping from mineral coal, and are so offer the cause of fatal accudents in mines, always contain serbours acid, carbiretted hydrogen, nitrogen, and desiast gas. The disengagement of all these rapidly insistential ordinary of bituminous coal into antiractic, to which the names of splint coal, hard coal, and many others, have been given." Mineralogists commonly divide coal into the non-bituminous and the blasminous. The non-bituminous variety includes antiractic, is coal with a bright lustre, often submetalic, iron-biact, and trequently indescent, it is opaque, the insistent being

Coal

conchoidal; usually it contains 60 to 60 per cent, of carbon, 4 to 5 of water, with some castly impurities, anthractice differ much in beginning and readiness of combustion. Forest note is an American variety, more compact than artificial coles, some kinds containing considerable bitumen; its origin is attributed by Genth to the action of a trap artiplica on bituminous coal. Cales is a kind of anthractic shale; in parliamentary returns the term is made use of to designate anthractic. Of oftensions coal there are saveral varieties. Pitch, or astring coal, when bested, breaks into small places, which, on the heat being raised, unite in a solid mass; its colour is velvet-black, or greyish black; specifingsravity, 1 289; it burns readily with a yellow fame; but requires fraquent stirring to prevent its raking, by which the ingress of air for combustion is prevented. Caking coal containing about 87 per cent. recrice. Caking coal containing about 87 per cent. t shundant product of the British coal-measures. mry soal resembles caking coal, but does not coften ke when heated : it is very frangible; and hence, and cake when heated: it is very frangible; and hence, in mining it, there is considerable waste. Near Birmingham, the loss in mining, including the pillars, amounts to two thirds of the whole. It burns more rapidly than caking coal, with a clear yellow flame. Soften coal is a dry coal, harder than cherry coal: it is a cearne kind of chunel you. There are other varieties which are still less biruminous; the finit coal, which are still less biruminous; the finit coal, which are still less biruminous; the finit coal, which approaches authracite, being of this kind. The first coal of Wednesbury, in Staffordshire, is of a similar nature; and the crow coal of Cumberland, at Alston Moor, is almost without bitumen. Cannel coal has a dark greyish-black or brownish-black colour, a fine compact texture, a large conchoidal fracture, and receives a good polish. It abounds at Lesmahago, about twenty miles from Glasgow; also in different parts in Ayrahire, where it is made into inkstands, and boxes, and similar articles. It is obtained in clear rectangular blocks of smooth and perfectly clear ce. It is remarkable for the readiness with which it kindles, being lighted at once in the flame of a lamp, and continuing to burn with a clear yellow flame without melting and running down. This property renders it well adapted for illuminating purposes, and has extract for it the name of cannel, which is the promunication of the word candle in Lancashire, where the name was first applied. This variety is found in the United States of America, in Western Pennsyl-vania, in Virginia, Ohio, Kentucky, and Missouri, rania, in Virginia, Ohio, Kentucky, and Missouri, sometimes in beds of considerable size, but oftener forming layers in the bede of the common bituminous cost. Jet resembles cannel coal, but is blacker, and has a more brilliant lustre. It occurs in detached bas a more orman number. It is the guarder of pieces in clay on the coast near Whitby, in Yorkshire, it is the guarder of Dioscorides and Pliny, a name derived from the river Gagas, in Syria, near the mouth of which it was found. Brown coal is more recent in of which it was found. Brown coal is more recent in origin than the Carboniferous era of the geologists. It sometimes resembles common bituminous coal. Other varieties have a brownish-black colour, bright coallike lustre, with something of the texture of wood re-

maining; and often, as when the form and fibre of like original tree is retained it is turned Hypote, which may be regarded as wood in a process of charge. It is the least rich is carbon, containing not more than 60 or 70 per cent. Coal, shemically considered, is need pas of the most important of mineral products. Whether we consider the enormous number of useful materials extend to the most important of mineral products. consider the enormous number of media makes tracted from it by chemical means, or the wast a of light shed upon obscure points of absenced during the investigation of the properties of products, it still remains the most reliable interesting substance, both to the practical maturer and to the chemical philosopher, that has been bestowed on man. Extensive beds of the conference of the con been bestowed on man. Extensive seem of many coal occur in Great Britain, covering about one to of the whole area, or 11,859 square unites, in Fair in Spain, in Belgium, covering about one twee second the whole area;—in the Netherlands, Frank Austria, Northern Italy, Spain, Russis on the so near the Azof. It is found in Asia, abundantly Chins, in Persis, in the Cabul territory, and in China, in Persia, in the Cabul territory, and an Khorassan, or Northern Persia; in verticus parts of India and Upper Assum; in Borneo, Labran, Samatra, several of the Philippine islands, Formoss, Japan, New South Wales, and New Zeeland. In America, besides the United States, in Chill, at the Straits of Magellan, on Vancouver's Island, as well as in the British provinces of Nova Scotia, New Brunswick, and Na-Saundland. In England the principal coal-Midda Newfoundland. In England the principal coal-fields are the Manchester, of Lancashire and Cheshire; the Great Central, of South Yorkshire, Nottingham, and Derby; that of South Wales, Glamorganshire, &c., and the Newcastle field, of Northern England. In Scotland a range of beds extends from the Firth of Forth to the Firth of Clyde, over an area of 1,450 aquare miles. In Ireland there are the Limerick fields, about the mouth of the Shannon, the Kilkeuny fields to the eastward, and those of Ulster in the north. In the United States there are four extensive coal areas: one of these areas, the Appalachian coul-field, commencies on the north in Pennsylvania and South-eastern Chic, and sweeping south over Western Virginia and Eastern Rentucky, and Tennessee, it continues to Alabams. It has been estimated to cover 65,000 square Alabams. It has been estimated to cover 60,000 equate miles. A second coal area (the Illinois) lies adjoining the Mississippi, and covers the greater part of Illinois, the western portion of Indians, and a small northwest portion of Kentucky. A third occupies a portion west portion of Kentucky. A third occupies a portion of Missouri and Iowa, west of the Mississippi. A fourth covers the central portion of Michigan. Besides these, there is a smaller coal region in Khode Leland, which crops out acrops the north end of the island, and appears to the northward as far as Manafield, Massachusetts. Beyond the borders of the United States on the north-east commences the coal area of Nova Scotia and New Brunswick, which covers, in connection with Newfoundland, 18,000 square miles, or two units of the whole area of these provinces. R. C. Taylor, in his extensive work on coal, gives the tollowing table, showing the proportional areas of coal land in Europe and America :-

	Entire Area in each Country.	Area of Coal Land,	Proportions of Coal to their whole Areas.	Relative parts in 1,000 of Coal Access.

In the sectrostred intilation of coal its elements com-biles smoone themselves to form a variety of useful stances, such as water, &c. Among these products, according to the temperatures em-bosides the carbonaccous residue called soke, and the 520

coal gue used for illuminating purposes, may be named oral ter, naphtha, naphthaline, paradine, benzole, coal oil (called by Dr. Lyon Playfair "liquefled coal gas"), and several other compounds. A description of these substances and the products obtained from them will be found under their respective heads. "Coal is of all minerals the most valuable, as it involves the employment of the largest amount of human labour and leads to the most important results. By it we obtain heat and light for all the insin purposes of life, and without it none of the modern contrivances for rapid fecometion would be available. Although by no means remous it none of the industrial contributes for rapid flocomotion would be available. Although by no means the only fuel, it is so convenient, so portable, so cheap, so readily transported without serious injury, and so abundant, that we could hardly carry on any of our most profitable manufactures in this country without it. The great coal-mining districts are, almost without exception, the seats of our industry in iron, clothing, glass, pottery, and other manufactures, for the soie reason that fuel is the most essential of all minerals, and that its price governs the cost of manufacture."

Brande's Dict. In mining for coal, the first process is that of boring, whereby the existence and depth of a bed of cost are ascertained. Afterwards a shaft is sunk for working the mineral; suitable hydraulic machinery is working the mineral; suitable hydraline machinery is set up for the purpose of draining off the water, and the sides of the shaft are securely faced with masonry of jointed ashlar; or, when the alluvial crust of the mine is formed of soft wet earth, the sides are kept up by planks of oak. Should there be much water in the mine, a shaft must be sunk for the express purpose of pumping it off. In this case, a second shaft is sunk for the raising of the coal, and as an upcast for the ventito coal-mining in the last edition of Ure's Dictionary of Arts, Manufactures, and Mines, says: "The most approved arrangement of shafts for a large colliery yielding explosive gas, and where water has to be pumped, is to sink a shaft for pumping, another for raising coals, and a third for ventilation or upcast, at the bottom of which is kept burning a large furnace. the bottom of which is kept turning a large nurnace.

... In British practice there are four different systems of working coal-mines. 1. Working with pillars and rooms or boards, styled post and stall, where the pillars left bear such proportion to the coal excavated as is just adequate to the support of the incumbent strata. 2. Working with post and stall, where the pillars are left of an extra size, and stronger than may be requisite for bearing the superior strata with the intention of removing a considerable portion of each massive pillar, whenever the regular working of post and stall has been finished in the colliery. 3. Working with post and stall, or with comparatively narrow rooms or boards, whereby an uncommonly large proportion of coal is left, with the view of working back towards the pits, whenever the colliery is worked in this manner to the extent of the coal-field, and then this manner to the extens of the constant and taking away every pillar completely if possible, and allowing the whole superincumbent strate to crush down and follow the miners in their retreat. 4. Working the long way, being the Shropshire and Derbyshire method, which leaves no pillars, but takes out all the coal progressively as the workings advance. On this plan the incumbent strata crush down, creeping very than the control of the cont plan the inclineers strate crush down, creeping very close to the heads of the miners. The post-and-stall system is practised with coals of every thickness. The long-work method is adopted generally with thin coals; for, when the thickness exceeds six or seven fact, and there is only little refuse made in excavating the coal to cast into the excavated part, this mode has been found impracticable." As a rule, the shaft of a miss is circular, and is, according to circumstances, from five to ten feet in diameter. When the first workable seam of coal is reached, the process of pitsinking is for a while discontinued, and a wide straight passage, called a "bord" or "gate," is opened up in opposite directions. This passage opens up the whole height of the seam of coal. When this bord has been excurated some distance into the sides of the pit, nar-row passages, called "headways," are driven from it row passages, called nearways, are driven from it at right angles. These passages are made to connect with other bords which have been opened up parallel with the first, or "mother-gate." By proceeding in this way, the entire bed of coal will, in time, be excavated, the roof of the mine being supported by in-521

mense square or rectangular pillars of coal left standing between the passages. During these operations the water has to be drawn off to the surface by the aid of a powerful steam engine erected above the shafe. of a powerful steam engine erected above the shafe. This engine also raises the coal and rubbish. In mines where "fire-damp" is not ferred, the pitman works by the light of a candle stuck in a piece of moist clay; but where explosions have to be guarded against, the safety-lamp is used. When the pitman who excavates his way through the bord has brought down a sufficient quantity of coal, it is conveyed to the surface, where it is frequently passed over screens, in order to separate the large lumps from the smaller and more pulverized coal. The number of collieries in existence in the year 1866 was 3,188. In the year 1863 the number reached no higher than 2.307. There 1953 the number reached no higher than 2,397. There 1953 the number reached no higher than 2,397. There are twelve inspectors of collieries; one for the north division of Durham, Northumberland, and Cumberland; one for South Durham; one for Derby, Notta, Warwick, and Leicester; one for Cheshire, Shropshire, and North Stafford; one for South Stafford; one for North and East Lancashire; one for St. Helens and Wigan district of Lancashire; one for So Helens and Wigan district of Lancashire; one for North Wales; one for the south-west of England and South-East Wales; one for Glamorganshire and South-West Wales; and two for Scotland.

COAL-PISH (Cadus carbonarius), a somewhat common Coll. First (cause carronaries), somewhat common fish, extensively distributed through the principal seas of Europe, being abundant in the Baltin, the Mediterranean, and the Northern seas; also found in large quantities on the coast of Great Britain. According o Mr. Couch, "It is in the highest condition from October to December, at which season it prowls after prey in large companies; so that, when met with, they prove a valuable capture to the fisherman ; for, though but coarse food, yet, being wholesome, substantial, and cheap, they are eagerly purchased by the poor, either fresh or salted. . I have known four men in two boats, two men in each boat, take over two tons weight boats, two men in each boat, take over two tons, weight of this fish in a very few hours. The season for spawning is early in spring; immediately after which the coal-fish becomes so lank as to be worthless, in which state it continues through the summer." It owes its singular appellation to the curious nature of its skin, which, upon being handled, soils the fingers in the same way as would result from touching coal. It is likewise known, during its progress from birth to maturity, by the names of cuddy, sythe, and sillock. The fishermen of Yorkshire, however, have given it two more aliases: when young, they call it purr, and the old fish are named lillets.

COAL FORMATION. (See CARBONIFEROUS SYSTEM.)
COAL TAR. (See TAR.)
COAL TRADE.—There is reason to believe that the existence and the use of coal in Britain were not un-known to the Romans. During the Saxon period, however, it seems to have been neglected. In 1239 Henry III. granted a license to the burgesses of Newcastle to dig for coal; and half a century later that town had become famous for its trade in this article. In 1306 the use of coal had become so general in London that the air was said to be infected with its noxious vapours, and its use was prohibited. In 1325 coals began to be exported to France, and in 1379 a duty of 6d. per ton was imposed upon ships coming from Newcastle with coals. In 1816 the coal trade at Newcastle appears to have employed four hundred sail; some of which went to France, others to the Netherlands. The which went to France, others of the Nethermans. In the coal trade of this country was long subjected to very heavy and oppressive duties. Formerly a duty of 6s. 5d. per ton upon large, and Is. 8d. per ton upon small coals, was levied upon all coal exported to foreign countries. In 1931 these duties were considerably modified, and in 1935 they were repealed, with the exception of an ad valueum duty of 10s, per cent. on exception of an ac caterine duty of 198, per cent. On coal exported in British vessels, and as per ton when exported in foreign ships. In 1840 these daties were altered to 108 ed. per cent, and 4s. 27d. per ton respectively. In 1842 duties of 2s, per ton on large and is, per ton on small coal and culm exported in Buttish vessels as in case of the comment of the comments. British vessels, or in vessels of foreign countries with which reciprocity treaties existed, were imposed, and 4s. per ton on such as were exported in other foreign vessels. The two former duties were abolished in 1845, but the last continued in force till 1850. In the

**s** 3

# Coalition

reign of William III. stax of 5s. per chaldron (53 owt.) was laid upon all cost carried constwise from one part of the kingdom to another, and during the French war it was raised to 9s. 4d. In 1825 this tax was reduced to 0s., and in 1831 it was repealed. Though these duties are now abolished, the coal trade is still in some places burdened with heavy local duties. By 1 & 2 Will. IV. c. 76, several oppressive acts affecting the coal trade of the city of London were repealed, and the duties previously payable to the corporation of the city more coals were communed for a duty of of the city upon coals were commuted for a duty of is. Id. per ton, and by 8 & 9 Vict. c. 101, a like duty was imposed upon coal brought into London by railway, causi, or other inland carriage. Not less than 85,600,000 tons of coal are raised annually from the sarious mines of the United Kingdom, and even at that Tate it is estimated that the supply will last for 1,000 years. England furnishes nearly 48,000,000, Wales about 5,500,000, Scotland nearly 9,000,000, and Ireland only about 120,000. Of these the greater part is either used in the vicinity of the mines or sent by inland burgingation or land-carriage to different parts of the lingdom. The total quantity of couls, einders, and culm sent coastwise to different parts of the United Kingdom was, in 1858, 9,525,811 tons; in 1860, 10,720,716. The quantity exported from the various ports of the United Kingdom to foreign countries and British possessions, where the contract of the United Kingdom to foreign countries and British possessions, where the contract of the United Kingdom to foreign countries and British possessions, where the contract of the United Kingdom to foreign countries and British possessions. ssions abroad was, in 1858, 6,529,483 tons; in 1860, 7.321,832. The country that received the largest quantity was France, amounting, in 1859, to 1,391,009 tons. In 1860 the total quantity of coals brought coastwise an asso the total quantity of coals brought coastwise into the port of London was 3,573,377 tous; by inland navigation and land-carriage, 1,409,899. There is much reason to doubt the policy of permitting the export of coal to foreign countries free of duty. "Taking into account," says M'Culloch, "that coal is the mainspring or causa causans of our manufacturing pre-eminence, we have always regarded the repeal in 1845 of the duty of 4s. (?) a ton laid on it when exported, as being in all respects a most impolitic measure. The retention of respects a most impolitic measure. The retention of the duty would not have perceptibly affected the exportation of coal, at the same time that it would have yielded a considerable amount of revenue derived wholly from the foreigner." "There does not seem to ready from the toreigner. There does not seem to be any ground for doubting that supplies of English coal are, if not indispensable, of the greatest value and importance to France, and study other foreign states." "There cannot, in our view of the matter, be s doubt that it should be charged when exported with a duty of 5s., or rather 6s. or 7s. a ton. Such a duty would not be innocuous merely, but advantageous, and would probably produce above £2,000,000 a year."—Supplement to third edition of M'Culloch's Commercial Dictionary

COALITION, ko-al-ish un (Lat. coalesco, I grow together), denotes the conjunction of parts which had before been separated, into one whole. In the beginning of the French revolution, it came to be used by French anthony has been considered to the control of th by French authors by way of contempt for the confederation of the other powers against France, the word alliance probably appearing to them too digni-fied for the object. Since that time the word has come into common use; but there is generally some idea of reproach implied in it. Continental diplomatists make this distinction between alliance and coalition,-that the former is more general, while the latter is directed against a particular enemy for a paracular opposition is also frequently used in the sense of a union of several parties, or their leaders, against another party; but it still carries with it the idea of reproach.

Coast, koast (Lat. costa, Fr. cots), a sea-shore, or the country adjoining the edge of the sea. When they are bordered with small rocks nearly on a level with the surface of the water, coasts are very dangerous. The depth of water is usually in proportion to the height of the rocks on the coast; so that a high coast indicates deep water, and a low coast shallow water.

Constitute Trade, koast ing, is commercial inter-course carried on by sea between different ports of the same country. Different laws regulate this department of trade in different countries, and, gene-tally, the policy has been maintained of excluding foreigners from all participation in it. This policy

# Cobalt

was adopted in England in the reign of Elizabeth, or, perhaps, earlier, and was perfected by the navigation acts of 1651 and 1660. These were succeeded by a vast number of regulations at different times; and by the Customs Consolidation Act (16 & 17 Vict. c. 107), it was enacted that no goods or passengers should be carried coastwise from one part of the United King. dom to another except in British vessels. In the following year, however, this restriction was repealed, and the trade is now free to the vessels of all countries. The number of vessels employed in the coasting trade The number of vessels employed in the coasting trade of the United Kingdom during the year 1868 were, entered, 142,528 vessels, of 18,490,546 tons, British, and 620 vessels and 107,571 tons, foreign vessels; and cleared, 143,146 vessels, of 18,593,120 tons, British, and 146,245 vessels, of 18,577,691 tons, foreign vessels.—

COAT OF ARMS. (See Heralder.)

COAT OF MAIL. (See MAIL, COATOF.)

COBALT, ko'-baudt (Germ. koboids, from koboides, the name of cortain mischivagus demons who were

the name of certain mischievous demons who were supposed to haunt mines, and to manufacture those ores which looked rich to the eye, but were really of little value. Among these were supposed to be the ores of this metal, and hence its name), Symbol Co, equivalent 29°5, spec. grav. 8°5.—Cobalt is a metal very similar to nickel in its physical and chemical properties. It generally occurs in the same ore as nickel, and the separation of the two metals is a task requiring and the separation of the two metals is a task requiring great patience and expertuess. Cobat is obtained as a metal either by reducing the exide by hydrogen, or by calcining the exalate. In the metallic state, it closely resembles steel. It fuses with great difficulty, and exidizes at a high temperature. It remains unstrend in moist air, dissolves slowly in sulphuric and hydrochloric acid, but readily in nitric acid. It is reddish-grey in colour, and is said to be magnetic. It is obtained principally from two ores,—Speiss coball and coball glauce. The compounds of cobalt are remarkable for their beauty of colour. The two colours may be the two colours and colour the two colours. and cobalt glance. The compounds of cobalt are re-markable for their beauty of colour. The two colours zoffre and smalt are compounds of cobalt. Zaffre is an impure oxide of this metal, made by calcining the crushed ore in a reverberatory furnace. The sulphur and arsenic are thus reasted off, and the impure oxide remaining is ground to an impulpable powder with two or three parts of fine and. Zafire is used largely in the manufacture of stained glass and in the ornamentathe manifecture of stained glass and in the ornamenta-tion of pottery. Smalt is a finely-powdered blue glass coloured with cobalt. Cobalt are is partially reasted, and combined with an equal quantity of carbonate of potash and twice its weight of well-ground quartz. The whole is melted in suitable pots in a furnace, silicate of potash being formed, in which the oxide of co-balt melts, the offer impurities falling to the bottom. The clear bine glass is ladded out, poured into water, and ground, when cool, into an impalpable powder. Smalt is used by paper-stainers. With oxygen, cobalt forms a protoxide and a sesquioxide. The anhydrous protoxide is obtained by calcining the hydrate or car-bourts. It is a black parader which the head size and bonate. It is a black powder, which, when bested in the sir, changes into an intermediate oxide, Co.O.. Oxide of cobalt gives to glass a very intense blue, which resists the action of as a very high temperature. Dissolved in ammonia, it gives a fine red liquid. Fused with potash, a brilliant blue compound is obtained. With magnesis, alumins, and exide of zinc, it produces, when fused at a high temperature, pink, blue, and green compounds. The last two are used as pigments. The hydrated oxide is a pink precipitate thrown down by adding a solution of potash to the solution of a cobalt salt. Protoxide of cobalt forms salts with the acids, which are light the air, changes into an intermediate oxide, Co.O. of could forms salts with the acids, which are light blue when hydrated, but turn red when the water is driven off by heat. Protonitrate of could is obtained driven off by heat. Protonitrate of cobait is obtained by dissolving the oxide or the metal in nitric acid. It crystallizes in small deliquescent crystals containing six equivalents of water. A solution of this salt is six equivalents of water. A solution of this saft is often employed as a sympathetic ink, being light blue, when cold, but bright red when the water of hydration is driven off by a gentle heat. The sulphaft of cobnit is generally employed as the source of safts of this metal. The esquioxide of cobalt is a brownish powder obtained by passing chlorine through a dilute solution of potash, in which the protoxide is mechanically suspended. Its salts are at present nuknown. Chloride

# Cobalt Ores

of coost is prepared by dissolving the oxide in hydro-chloric acid: the pink solution resulting yields, on evaporation, rose-coloured octahedrs of the hydrated chloride. The other saits of cobalt are uninteresting.

A solution of the nitrate is used in blowpipe analysis. A small quantity of the substance to be examined is to be moistened with the solution, and heated in the blowpipe finne: a pink colour indicates magnesia, and en and blue, zinc and alumina respectively. Fremy agreen and blue, zinc and alumina respectively. Frein, has formed some interesting compounds by combining the escutionide of cobalt with four, five, and six equivalents of ammonia, forming brown, red, and yether sales. These double bases he names fuscobaltia, researchaltia, and luteocobaltia. Thémard's blue is a low saits. These double bases he names fuscobaltia, resecobaltia, and lutescobaltia. Thenard's blue is a beautiful pale-blue pigment, consisting of a mixture of phosphate of cobalt and phosphate of alumina.

COBALT ORBS. - The principal ores of cobalt are, white colatt Osss.—Ine principal ores or cooms are, waite solutions, which is the most common (it contains coluit associated with arsenic, iron, and sulphur); grey cobalt ore, containing arsenic, iron, cobalt, and silica; and glance colat, which is a double bisulphide of arsenic and cobalt. All the ores of cobalt contain more or less

COBALTICYANOGEN. (See CYANOGEN.)
COBALTINE, ko-bawlt'-een, in Min., an arsenical ore of cobalt, also containing sulphur. It occurs in reddish silver-white trapezohedral crystals, at the mines of Webna, in Sweden. It contains from 33 to 37 per cent. of metal.

COBRA DI CAPELLO. (See HOODED SNAKE.)

COCA. (See ENTHROXYLON.)
COCCAINN, kok-set-gins, was a theological school which arose towards the middle of the 17th century, and took its name from its founder, John Cocceius, professor of divinity in the university of Leyden. He regarded the history of the Old Testament as a mirror which held forth an accurate view of the transactions and events that were to happen in the Church under the dispensation of the New Testament, and unto the end of the world. The greater part of the ancient prophecies, he maintained, were to be received in a literal manner, and by the very sense of the words used in these predictions. In fact, his whole system was an attempt to Judaize Christianity. He was a man of considerable learning, and he has most fully expounded his views in his "Summa Doctrine de Fædere et Testamento," Leyden, 1649. His great opponents were Desmarets and Voetius. His views found for a time many supporters in Holland and other parts.

COCCILOBA, kok-ko-lo'-bu (Gr. kokkos, a berry ; lobos, a lobe), in Bot., a gen. of plants belonging to the nat. ord. Polygonaceæ. From the leaves, wood, and bark of C. unifera, a very astringent extract, commonly known as Jamaica kino, is obtained. The fruit called the seaside grape is edible, and has an agreeable seid

flavour.

navour. COCCOSTEUS, kok-kos'-te-us (Gr. kokkos, berry; osteon, bone), in Geol., a fish of the Old Red Sandstone, so named from the small berry-like tubercles with which the plates of its crauial buckler and body are thickly studded. The remains found in the Caithness flagstones show that its length was from a few inches to about

COCCULUS INDICUS, kok'-u-lus in'-di-kus (Lat., Indian berry), is the fruit of the Anaminta paniculata (which see). It has some resemblance to the bay-berry, and is imported into this country from the Eastern archipelago. In 1850 no fewer than 2,359 bags of one huntrindwich each ware precised. Cocculus indians in dredweight each were received. Cocculus indicus is chiefly used for adulterating cheap beer; and it is really wonderful in how many ways it is fitted to disguise a liquor prepared from insufficient quantities of malt and hops; thus, it impurts to the sophisticated liquor an intensely bitter taste, a darkness of colour, and a fulness of body, while it adds to its inchristing qualities. It is scarcely necessary to state that the occulus is never employed by respectable brewers. Its use has been forbidden by act of parliament under a penulty of £200 to the brewer, and one of £500 to the druggist of 2200 to the prewer, and one of 2500 to the druggest who sells it to a brewer. In large doses it is poisonous to all suimals, and it has long been used by poschers for stupifying fish and game. In medicine it has been employed as an external reflectly for certain skin diseases. It owes its active properties to a very poisonous crystal-ling alkaloid called picrotoxine. The names Levant mut Cock

and Bucca orientalis are sometimes applied to this

COCHINEAL, kotech'-in-eel (Sp. cochinilla).-beautiful dye is obtained from the Cocess cuce, a beautiful dye is obtained from the Louiss of the insect intesting a tribe of carti growing in Honduras and other parts of South America (see also Carmera). and other parts of bound america (see also Carmaines). The femals insects, which are wingless, are also so delected, and the different degrees of value attached to them depend on the methods employed to kill and dry the insects. Analyses of cochineal have yielded chiting. fatty matter, phosphates of lime and petash, and the colouring matter carmine. Cochinest, in conjunction with chloride of tin, forms the "tin spirits" of the dyer. The coclineal insect is also cultivated in Mexico, Teneriffe, Java, and the West Indies. Efforts have been made, with more or less success, to introduce it into Van Diemen's Land, the Cape of Good Hope, Algeria. and Spain.

and spain.

Cochierer, kok-le-air'-e-ā (Lat. cochleore, a spoon),
in Bot., a gen. of plants, so named from the leaves being
spoon-shaped, belonging to the nat. ord. Crucifers. The
species C. officinalis is the common scurry-grass, an indigenous annual found in muddy places near the sea-shore. It has white flowers, which blossom in April and May. When rubbed, it evolves a pungent odour, and its taste is acrid and penetrating. It has long been esteemed for its aniscorbutic properties, and was formerly admitted into the Dublin Pharmacopois.

merly admitted into the Dublin Pharmacoposis.

Cock, Domestic, kok (Sax. coc, Fr. coq), (Fallow domesticus).—At what period of the world's history this valuable bird was brought under the control of man, it is almost impossible to determine. Without doubt, they were well known over many parts of Europe and Asia many hundred years before the Christian era. Pliny, in speaking of it, says.—"After the peacock, the birds which are most sensible to-clary are those active sentingle which are most sensible to glory are those active sentinels which nature has produced to rouse us from our matin slumbers and send us to our daily occupations. They are acquainted with the stars, and every three hours they indicate by their crowing the different periods of the day. The gatt of the cock is proud and commanding; he walks with head erect and elevated crest. Alone of all birds he habitually looks up to the sky, raising at the same time his curved and scythe-formed tail, and isspiring terror in the lion himself, the most intrepid of heasts." A mode of divination was practised by the ancient Greeks with these birds. The letters of the alphabet were written in a circle, and a grain of wheat and barley laid on each letter. Then a cock, consecrated for the occasion, was led within the circle. The required informstion was obtained by putting together those letters of which the cock picked the grains. This mode, however, was abandoned on the discovery that it was not an uncommon thing for the priests to have, as well as the genuine grains, imitations in war; so that by proper management the bird could be made to uncover those letters that best accorded with their views. It has been asserted that our original breeds of do-mestic poultry were derived from Persia. This, bow-ever, takes root in the fact of Aristophanes allading to the cock as the "Persian" bird. This is, in to the cock as the "Persian" bird. This is, in all probability, but a hinting at the fact that during the intercourse of the Greeks with the Persians, they the intercourse of the Greeks with the Fersians, they obtained from them a breed of fowls partly or thoroughly domesticated. Although poultry has been known to exist in Fersia from a very remote antiquity, the most patient research has failed to discover any birds of the genus Gallus in that country. According to Temminck, our domestic cock is derived from the Jago cocks (Gallus giganteus), a large and wild species inhabiting the island of Surnatra, and from the species Bankiva, another primitive bird found in the Javan forests. Nor is this argument without substantial basis; for the size of our common cock is intermediate between the Jago and the Bankiva, and in the nature of the feathers and the distribution of the barbs the resemblance is perfect; moreover, in the two wild species mentioned, the females are provided with a crest and small barbles,—characters which are not found in any other known primitive races. The domestic cock has his head surmounted by a notebed crimson fleshy substance, called a comb; and under the threat hang two other pendulous fleshy bodies, called wattles. In both sexes there is below the est

# Cockede

an eblong spot, the interior of which is reddish and the remander white. The feathers arise in pairs from each sheath, touching by their points within the skin, saon aneath, touching by their points within the skin, but diverging in their course outwards. On the neck the feathers are long and marrow; on the rump they are of the same form, but droop laterally over the extremity of the wings, which are quite short, and terminate at the origin of the tail, the plumes of which are vertical. In the centre of the cock's tail are two long feathers, which fall back in a graceful arch. When the cock reaches the age of six months, he attains marries and his wowere remain undiminished till he is tarity, and his powers remain undiminished till he is tires years old. Then, if younger male birds be about, he will find himself alighted by his numerous wives, and be compelled to yield to a rival the empire of the yard. Descripting is one of the most widely-spread sports in the world. Captain Cook fighting is one of the most widely-spread sports in the world. Captain Cook found it commonly practised among the South-Sea Islanders, and Mr. Ellis describes it as one of the most ancient games among the Ekhtisians. Long before a ship touched the shores are the surface and industrial to the inhabit. of Polynesia, cock-lighting was known to the inhabitants. Amongst them, however, the rules that distinguish the "civilized" cockpit are not practised. Its, or, happily, was, our custom to clip the combatants of every superfluous feather; the Polynesians, on the contrary, delight to pit them with the full complement of plumage adorning them. In another respect, too, these savage cock-fighters showed themselves more humane than us: they never armed the heels of their birds with spurs; and as soon as one bird was observed to wood his antagonist, he was said to be vi (besten), and at once taken away. The common jungle-fowl of continental India (Gallus Sonneratii) is a very favourite continental India (Gattus conneration) is a very instance. If the Mussulman natives of India. (See Cook-righting.) Considering their insignificant means of defence, the courage exhibited by the domestic cook is very singular. Bishop Stanley, in his mestic cock is very singular. Bishop Stanley, in his British Birds," says, "We knew an instance where a barn-door cock became the terror of his little domain. Accustomed to be fed by his owner, a clergyman, he shortly began to express his disappointment by very determined attacks, if his master happened to pass him without the accustomed offcring. On one occasion he actually struck a piece out of a strong kerseymere gaiter, and repeated the attack in spite of some severe kicks it was found necessary to inflict in self-defence. Nothing departed though occasionally histed defence. defence. Nothing daunted, though occasionally kicked several yards like a football, he would still come on as fiercely as ever for three or four times. His reasoning, too, appeared to be on a par with his courage, for he soon discovered that women were protected by the

soon discovered that women were protected by the lower part of their dress, and, accordingly, instead of flying at their legs and feet, he invariably flew at their heads, fixing himself on their shoulders. Cockans, kok-aid! (Fr. cocarde, a corruption of coquarde, a tuit of feathers), is applied to a mark of distinction wom on the hat, usually a riband or a knot of ribands, properly by officers of the army or navy, or their gervants, but frequently assumed by others. It is disconstinues the budge of political party.

Cockarde, kok-a-tooz'.—These birds are confined to the Eastern Archipelago and Australia; in the latter country they are very abundant. Like others

latter country they are very abundant. Like others of their congeners, they make their nests in decayed of their congeners, they make their nests in decayed trees; indeed, if the tree should not be very much decayed, it makes little difference to the cockatoo, who can speedly dig for himself a hole in the trunk with his iron-like bill. They are easily tamed, and learn to imitate the human voice in some respects, although with little accuracy. A capital account of cockatoo-hunting by the natives is related by Captain Grey:—"Perhaps as fine a sight as can be seen in the whole circle of native sports is the killing of cockatoos with the their or homerous. A native processes a large with the kiley, or boomerang. A native perceives a large light of cockstoos in a forest which encircles a lagoon; at in the leafy summits of the trees sit a countless miniber of cockstoos, screaming and flying from tree to treess they make their arrangements for a night's sound Tree as they make their arrangements for a night's sound genus, discovered within the specimen was sent to Mr. Le may not have even, this slight covering to impede his in named. It is about fiftee motions, draws his kiley from his belt, and, with a noiseless elastic step, approaches the lagoon, creeping from tree to tree, from bush to bush, and disturbing the birds as little as possible. Their sentincls, however, take the slarm; the cockatops farthest from the

### Cockboat

water fly to the tree near its edge, and thus they keep concentrating their forces as the native advances. They are aware that danger is at hand, but are igaorant of its nature. At length, the pursuer almost resches the edge of the water, and the scared cockatoos, with wild cries, spring into the air. At the same instant, the native raises his right hand high over his shoulder, and bounding forward with his utmost speed for a few pages, to give impetus to his blow, the filter for a few paces, to give impetus to his blow, the kiley quits his hand as if it would strike the water; but hen it has almost touched the unrufiled surface of the lake, it spins upwards with unconceivable velocity and with the strangest contortions. In vain the terrified with the strangest contortions. In vain the terrined cockatoos try to avoid it: it sweeps wildly and uncertainly through the air; and so eccentric are its motions that it requires but a slight stretch of the imagination to fancy it endowed with life, and, with fell swoop, is in rapid pursuit of the devoted birds, some of which are

LEMON-CRESTED COCKATOO.

almost certain to be brought screaming to the earth But the wily savage has not yet done with them. Ho avails himself of the extraordinary attachment which these birds have for one another, and fastening a wounded one to a tree, so that its cries may induce its companions to return, he watches his opportunity. its companions to return, he watches his opportunity, by throwing his kiley or spear, to add sucther bird or two to the booty he has already obtained." Of this bird there are several species; as follows:—Broad, or Rose-crested Cockatoo (Psittacus cristatus).—This is the largest of the cockatoos, being about two feet in length. It is distinguished from the other species, and the state of the cockatoos to the other species. which not only by its size, but also by its creat, is arched over the head, and of a bright orangered colour beneath. The general colour of this bird is white, with a pink tinge. It is sometimes domesti-cated, and learn to mimic the voices of various ani-mals with which it is domiciled or in the vicinity of which it is placed. It will mey like a cat, bark like a dog, or imitate, with marvellous correctness, the crowing of a cock,—Great Sulphur-crested Cockatoo (Psittacus galeritus),—This species is at the same time the handsomest and most common of the family. Its plumage is white, tinged with yellow on the tail and orange or lemon-colour on its crest, which is pointed, and about seven or eight inches in length. In Aus. tralia, these birds abound in large flocks of thousands They commit frightful havoc in the cornin number. fields, and the sight of this handsome bird is sufficient to create the utmost dismay in the mind of the agri-culturist, who knows too well the affinity betwixt ripe corn and the lemon-crested cockatoo.—Lesser Sulphurcrested Cockatoo (Prittacus sulphureus) .- Greatly resembling the preceding, only some few inches smaller. It is a native of the Moluceas; but of its habits little or nothing is known. It is very pretty, diffectionate, and good-tempered, a rare combination of excellent qualities. There is another species of the Cockston quantes. Inere is another species of the Cookaton genus, discovered within the last thirty years. A specimen was sent to Mr. Leadbeater, after whom it is named. It is about fifteen inches in length, of a white colour, tinged with pink. This species is exceedingly rare and greatly prized.

COCKBOAT, kok'-bote (Arg.-Bax.), a small boat used on rivers or near the shore, which is both too weak and too small for sea service.

Cockchafer

Coccon

COCKCHAPES, kok'-chai-fer (Ang.-Saz.), (Melolontha vulgaris), a well-known species of beetle, belonging to the Lomellicornia. At is very common throughout the greater purt of Europe, and in this country is particularly abundant. In its larvastate it lives for nearly four years, and fields, very voraciously, on corn, &c. The perfect insect has an exceedingly short existence, sometimes living only a week, and occasionally so long as a month, after arriving at maturity. At this stage it feeds on the leaves of various trees. The sycamore, the lime, the beech, and willow are most in requisition: these trees are sometimes completely loaded with cockchafers. In its depredations it more nearly resembles the locust than any other insect; and, at certain times, commits frightful ravages in agricultural districts. A remarkable instance of this occurred in Ireland about the year 1688. On this occasion, it is said, they hung in dusters on the trees and hedges, like bees swarming: the noise of their countless jaws at work was heard by every traveller, and was compared to that of the sawing of timber.

COCK-CROWING .--The vulgar belief that spirits are permitted to roam about the world in the night, and obliged to disappear at cock-crow, is very ancient, and oniged to disappear at cox-crow, is very ancient, and is mentioned by the Christian poet Pradentius, who flourished in the beginning of the 4th century, as being a common belief among the early Christians. The belief has not yet altogether died out; and Bourne tells us, that in the country villages, where the people require to go early to labour, they always go cheerfully at cook-crow; but if called abroad sooner, they are apt to imagine everything they see or hear to be a

wandering ghost.

COCKER, ACCORDING TO, kok'-ker, a phrase some-times applied to what is strictly correct, or according to rule. It is derived from a celebrated arithmetician of that name, who flourished in the 17th century, and was the author of a well-known work on arithmetic.

COCK-PIGHTING is said to have been a common pas time in Athens and other parts of Greece, and it seems to have been afterwards adopted from that country by the Romans. It is probable that cock-fighting was the komans. It is promine that cock-igning was first introduced into this country by the Romans, though the bird itself was here before their arrival. In the reign of Henry II. it was a sport of the school-boys on Shrove-Tuesday, and called Carnilevaria; but we have no earlier account of it. The same practice prevailed in many schools in Scotland to within the fast century. It became a great national sport; and last century. It became a great hardonal sport; and though more than once prohibited, it received encouragement and countenance from several of the crowned heads. The celebrated national cockpit at Westminster is said to have been erected by Henry VIII., and James I. and Charles II. were both encouragers of the sport. It was forbidden by one of encouragers of the sport. It was forbusen by one of the acts of Gromwell. At present, cock-fighting is prohibited by 12 & 13 Vict. c. 92, and a penalty of £5 may be levied on any person keeping fighting-cocks, letting a cockpit, &c., for every day that he shall so act; but it is still largely carried on, particularly in the colliery districts in the north of England. Cocks for fighting are selected with the greatest judgment, and trained with the utmost care. For the combat, they are care-fully trimmed and armed with steel or silver spurs. The place appropriated to fighting is called the pit, and the buttle is conducted by two setters, who place the cocks beak to beak. When once pitted, neither of the setters can tonch his cock so long as they continue to fight, unless their wespons get entangled. In what is called the "Welsh main," a number of cocks are pitted against each other, and then the conquerors pitted against each other, until only one remains alive. (For those that wish further information on this subject, we

unoso that wish further information on this subject, we may refer to Blaine's Encyclopædia of Rural Sports.)
COOKLE, kok'-l (Cardium), a gen. of Mollusca, belonging to the Cardiaceæ. There are numerous species of this animal, some two hundred of which are known. The common cockle is the most abundant, and large quantities of this shell-fish are found on the country of Casest Bullian subjects. and large quantities of this shell-has are found on the coasts of Great Britain, principally on muddy and sandy banks. By some it is considered a highly nutritions article of food; and, Indeed, the enormous demand for it would seem to justify such an opinion. The structure of the cockle is somewhat curious; it has two adductor muscles, which serve the animal to 523

draw the valves of the shell together. Its foot is very large, compared with the circ of the snimal, and beat in the middle. This member is not only used for the purpose of progression, but also for executing heles in the mud and sand in which it lives. By suddenly at raight and sand in which it lives. By success, straightening the foot, the cookle moves with a jump. As the foot is smaller than the shell, it may appear a little singular how it is enabled to bore a hole sufficiently large to admit the whole animal. This is accommended to the sufficiently large to admit the whole animal. This is accomplished by distending the foot with water, and then, by a rotary motion, the seemingly impossible feat easily achieved.

COCKNEY, kok'-ne, is a nickname, or term bf con-tempt, applied to a Londoner, and has been long in use, occurring in verse as early as the reign of Henry II Its origin is doubtful. According to some, it is derived from coquina, a kitchen, and denoted the luxuriousness for which London was celebrated even in early times; or from Cokeigne, or Cocagne (probably from the same root), the name of a Utopian country of luxury and ease. According to some, it denotes one coaxed or cockered, made a fool or nestle-cock of; secording to others, one utterly ignorant of rural affairs or hus-bandry. The latter probably originated in the wellhandry. The inter property who, when on a visit to the country, being told that the horse neight, afterwards spoke of the cock neighing, hence cocknets, cockney. The modern mark of cockneysm is an abuse wards spoke of the cook neighbor, account, and the cooking is an abuse of the letters h and r; as, hair for air, sofar for sofa. The Cooking school of literature was a term applied in the earlier numbers of "Blackwood's Magazine" to Leigh Hunt, Hazlitt, Keats, and other young authors. The King of the Cookings was an important personage in the sports and shows formerly held in the Middle Temple on Childermas-day, and had his mar-shal, butler, constable, and other officers, who were ordered to be entertained with due service in "honest manner and good order.

COCKPIT, kok' pit (Ang.-Sax.), in a ship of war, is a cabin situated near the apartments of the surgeon and his assistants, where all the men wounded in action are

conveyed to have their wounds dressed.

COCKROACH. (See BLACKBRETLE.) COCOA, or CACAO. (See THEOBROMA.)

COCOA, Or COCOA-NUT. (See COCOS.)

COCOA-NUT FIBER, ko'-ko.—The seeds of the socoanut palm (Cocos nucifera), well known under the name of cocoa-nuts, are contained in a large hust composed of solid woody fibres. These fibres were woven into fabrics of various sorts by the natives of Cevlon and India from time immemorial: but it is only within the last fifteen years that this material has only within the last fifteen years that this material has been used in Eugland. Cocca-nut fibre is now applied most successfully to the manufacture of mats, matting, cordage, brushes, brooms, &c. &c. &c. Latterly a method of introducing colour into the manufacture has been devised by dyeing the fibre; and some very fine combinations of colours have been formed, which contrast successfully with similar manufactures in the finest harm. Coreanut fibre has formed, which contrast successfully with similar manufactures in the finest hemp. Cocoa-nut fibre has been used for bedding with great advantage. It does not become knotty or hard, does not harbour vermin, and is not affected by variation of climate. The refuse of the husk forms a perfect material for fern-beds, being much less liable to give out an offensive odour than spent tan, which is often used for this purpose. Cocoa nut libre is also called soir, and has long been used for ropes and cordage under this name.

Cocoon, kok-own (Fr. cocon), the silky tissue or envelope which the larve of many insects spin, as a covering for themselves immediately before passing into the pupa form. The name is also given to coverings made of other materials. Some caterpillars work into the silky anythous the hairs which cover their into the siky envelope the hairs which over their bodies; others imbed in the network a leaf, or several leaves fastened together. The larvas of some insecta broduce the silken substance of which the cocoons are formed in much greater quantity than others. the most useful producers is the ordinary silkworm, whose cocoon is a close and compact oval ball, surrounded with a gauze-like glossy covering. It consists of one long continuous thread, sometimes a thousand feet long. Some parts of the thread are weaker than feet long. Some parts of the thread are weaker than others; but the greater portion can be unwound as easily as a ball of cetton thread. Different insects

milk) are important articles of food in many mauy tropical regions.

The cocoa-nut is

also largely con-sumed in this country. From

vary in the time occapied in animing their occouns: several days are spens by the silkworm in this task. In covering the pape, many insects preceed with an aimset mathematical injusty with regard to the direction and disposition of their threads.

Cocos, to less (Gr. kokkes, a kernel), in Bot., a gen of Palma C, and free, the cocos or cocoa nut palm, a perture the most useful member of that great family, in pertuage the most userin member of this great among which may be said to yield flour, sugar, oil, wax, wine, thread, attending timber for habitations, and leaves for thatching. The cocca-nut palm itself furnishes our tropical arretiren with most of their necessaries, and the said from the inice Sugar castled aggery, is largely obtained from the juice which dows out when its spathes and spadix are injured. Today and arrack are produced by the fermionation of this juice. The albumen of the seeds (2000s-suts) and the liquid within this (cocon-nut

mous quantities by Price's Candle Company. (See COCOA-NUT PALM. PACTURE.) .In India it is much esteemed as a pomatum for strengthening the hair; but its unpleasant odour, and its hability to become raudid, prevent its use in this country for such a purpose. From the fibrous portion of the pericarp of the cocca-nut, the strong fibres called corr, or cocon-nut fibres, are obtained. They are remarkable for their strength and durability, and are much used for cordage, fishing-nets, matting, scrub-bing-brushes, and similar manufactured products. The

sing-breames, and similar manutactured products. Inc.

mood of the cocca-nut palm is very hard, handsome,
and durable, and is applied to many useful purposes.

It is commonly called porcupine-wood.

Com, ked (Ang.-Sax.).—This fish is, perhaps, the
most important to the human family of all the
imbabitants of the deep. It affords labour and
food to the usual of men, and is one of the most splendid national resources,—one which, owing to the wonderful provision of nature with regard to the fecundity of this fish, is not likely to diminish for a someiderable period. For more than four certuries considerable period. For more than four centuries has the cod-fishery been carried on, without any interruption; yet the supply at the present day is something enormous. A single fisherman has been known to capture 500 of this fish in a day of ten bours. Now, explare-600 of this as in a day of ter hours. It was the of frequently attains a weight of 50 lbs., this had of the fisherman, even setting it down at a mode-rate rate, must have amounted to something like 20,000 lbs. of fish; and multiply this by several thousands, and we get the amount of cod which is daily desirated desirated has soon. The creat summly of cod obtained during the season. The great supply of codes from the banks of Newfoundland; but the codfisheries near the coasts of Scotland, Sweden, and Iceland, are by no means insignificant. The principal place in which it is found on our coasts are thus slined to by Mr. Yarrell:—"A change has taken place, from the cod having shifted their ground. Bornerly the Gravesend and Barking fishermen obtained few cod mearer than the Orkneys or the Dogger Bank; but, for the last two or three years, the supply for the London market has been obtained by going so farther than the Lincolnshire and Norfolk coasts, as even between that and London, where previously Clode

very few fish could be obtained." There are about 6,000 vessels employed in the cod-fishery, in addition to a large quantity of small boats. All the cod are caught targe quantity of small house. All the con are caught by hooks and lines; the bait used commonly consists of impets, whelks, and pieces of various lishes. Our wonder at the extraordinary supply of this fish is considerably diminished when we examine the roc of the cod. By those who have taken the trouble to satisfy themselves, it has been calculated that when one de-vours a cod's roe, he also devours no less than about 180,000,000 lbs. of food, supposing it were allowed to arrive at maturity. One's brain roels at the bars idea of reckoning what might be the condition of cod-dom of reckoning what might be the condition of wood-dom if these fishes were left alone for a few person. The soci is a very veracious fish, a good instance of which is related by Yarrell. "Mr. Crouch," says he, "has taken thirty-five crabs, none less than the size of a half-crown piece, from the stomach of a cod." It is not particular in its diet, but devours indiscriminately all the small

fish iŧ can The catch. modus operandi of the fishermen is thus described: -"For the deepsoafishing very long lines are used; - these are fixed to the bottom by means of

small anchor, the other end being supported by a buoy, and the hooks are placed at the extremities of short lines, usually about six feet in length, attached at intervals to the main line. The long lines are usually left for about six hours, or for a whole tide, when they are taken up and examined. In the interval the ishermen are not idle; they carry on the work of destruction by means of hand-lines, of which cach mnn manages a nim."—Dallas's animal Kingdom. ~

CODARIUM, ko-dd'-re-um (Gr. kodurion, a leathern pouch), in Bot, a gen. of plants belonging to the nat. ord. Leguminous, sub-ord. Censlpinies. C. acutifolium and obtusifolium, both natives of Sierra Leone, yield fruits known as the brown and the velvet tamarinds. The pulp of each kind is caten, and has an agreeable

CODE, koad (from Lat. codex, a manuscript), in Juris., is applied to a compilation of laws made by public au-thority. Several collections of the Roman law are designated by the name, the chief of which are, the Gregorian and Hermogenian codes, made by two colebrated jurisconsults, Gregorius and Hermogenes, and containing the constitutions of the emperors from Hadrian to Constanting: the Theodosian code, published in 428 by command of the emperor Theodosias II.; and the Justinian code, prepared by command of the emperor Justinian, and first published in 529, and a second time after revision, in 534. There are several of the modern systematic collections of laws designated by the title of code, the chief of which are the code of Frederick the Great of Prussia; that of Catherine of Russia (confined to criminal jurisprudence); that of Joseph II. of Austria; and the celebrated Code Name them in France. In France, before 1789, there was no uniform system of legislation; in some parts the Reman law prevailed, in others ancient custom, both being supplemented by royal ordinances. These having bei abrogated at the revolution, several attempts were made to form a code of laws in accordance with their ultered circumstances; but, on secount of the unsettled america circumstances; but, on account of the unsettled state of society at that period, nothing of a satisfactory nature was effected. At length Napoleon, after he be-came first consul, appointed certain commissioners to draw up a project of a civil code, which was printed in the early part of 1801, and copies thereof transmitted to the different courts of france for their observations. and suggestions. The whole was then laid before the legislative section of the council of state, and the rious points successively discussed, Napoleon himself

526

Codex

taking an active part in the debates. After being cub-intted to the tribunate, it was at length premaigated as the civil law of France in 1804. When Napoleon was reased to the empire, the tate Code sivil des Fran-cais was charged to Code Napoleon. In 1816 the former this was restored, and in 1852 the title Code Napoleon was again given to it. This code, which regulates the civil rights of the people, as regards person and property, in its general arrangement and distribution resembles the Institutions of Justinian. It is divided into three books, the first of which treats of the civil volutions of books, the first of which treats of the civil relations of Dooks, the next of which react of the fivil relations of individuals, the second of property in twa next kinds and modifications, and the third of the various modes in which property is legally acquired. Besides the Code coil, the French written law comprises five other codes. The Code de Providure cuide relates to the forms of pro cess and the modes of procedure before the various givil courts—The Code ne Commerce as its name in it civit courts—The Code de Commerce as its name in in cases, bear upon commerce al transactions. It consists of four books, the first of which treats of commerces general, of the various classes of commercial men, of partnerships, &c. the accord of maritime commerces, the third of bankripties, and the fourth of commer-cial knownia.—Code d'Instruction criminelle regulates the farms of procedure in crimical cases—The (ode penal defines the various kinds of crimes, and their several punishments. This and the preceding were promulgated in 1810, but important changes have been made upon them by subsequent enactments, particu isrly in 1832 —The sixth and last of these is the Code foresties, which was pullished in 1927, and relates to the administration of the woods and forests

Conex, ko der (Lat ), origin ally denoted the trunk of a tree, and was after wards applied to the wooden tablets covered with wax whi h weis used by the ancients for covered with war win h were used by the ancients for writing. It atterwirds came to be applied to a book or manuscript generally and under the emperors, and subsequently, it designated collections of civil and acclesiastical laws (over Copr). A very valuable invendants MKillop, the managing director of Sing-coating Company, has been tried and a successful. The object of the invention, semed the "Portable Cofferdam," is to prothe means of thoroughly examining or repairing at the ressel, from her keel to her water-line, submerged. The apparatus consists of a large when submerged. The apparatus consists of a large shapet of wiserproof carwas, at each end of which is a fainteer bag, which is filled with air on the carwas being handed taut under a vessel's side, when the whole is made air and-water-tight by the pressure on the outer surface. The volume of water contained in the interior of the carwas is then pumped out, and the carries being distended by a framework of iron, a dry

course with the containing the remember of iron, a dry space is kept clear to allow of men repairing any damage the ship in y have sustained.

Corrier, boy on (Gr. kophinos, a wicker basket), is a cheat or box for containing the remains of the dead. Coffine have been in use from very early times; and we are take that the body of Joseph was embalmed and placed in a coffin in Egypt. In that country coffine were usually made of pasteboard glued together, and covered with hieroglyphics; but sometimes these were also indicated in coffine of wood, stone, or eartherware. Among the appient Britons, stone coffins were sometimes employed for persons of distinction, and they are still constitution met with in barrows, together with Roman irms; and the kistvaen, or coffin composed of rough stone set edgewise, and overed with one or more flat stones, was common. We are told that, from more flat stones, was common. We are told that, from the 9th century to the reign of Henry III. and later, ne suffins were in general use for persons of the ever, were only wrapped in cloth, and so put into the ily in use among the Saxons. In some countries, as a Spain, the coffin merely serves the purpose of hold-ng the body while it is carried to the grave or tomb, d is then used to perform the same office for others. In the Bast the body of a deceased person is carried to the grave on a simple bier, without any coffin; and this custom prevails equally among Jews, Mohammediana, and Christians. This was also the practice among the encient Jews, as we know from the account of the widow of Nain's son.

e which r would tend to separate them. joined with much more case; cohesion is entirely overcome, the part one another instead of attracting. The one another instead of attracting. The for sion is weakened or destroyed by two genies either by heat, or by the attraction while exerted by the particles of one body on the another. When these powers—heat and chief tion—are withdrawn, otherior resumes in with results that are different, according cumstances under which the withdrawal of body which has been melted is suddenly takes the form of an irregular solid. If, colesion is exerted more slowly, the particles a united in regular forms. (See Currentultation After the particles of a body have been separated, a force of cohesion will make them require if they pressed closely together. Cohesion is the attre exerted by homogeneous or like particles, and difference from adhesion, which is the attraction exerted by heterogeneous or unlike particles.

COHORT. (See LEGION.)

COINAGE. (See MINT.)
COINING-MACHINE, a very beautiful machine for stamping money has been invented by M. Thompelier, which combines economy with perfection of workman ship, durability of the machine, and safety to the operatives. The moving power applied to a rather a steam power, turns a fly-wheel, which gove it, and sums up all its powers the moment a stamped. To the axle of this fly-wheel a spiral curve is adapted to direct the movements of a connectingrod, which transmits to the moving parts the men nism of placing and taking off the metal between the stamps, and withdrawing it when the money is stamped. The power accumulated by the five wheel is transmitted through its axle to a winch, which note upon two arms joined to each other by a hinge at their extremities, and forming a very obtuse angle, which can be opened or closed a little. When this angle is opened, the two other extremities of the arms or levers become more distant, and as the superior meets a buttress, it is the inferior one which moves: It is perly a funicular lever or mechanical knee. Thus, lower part of the inferior lever is drawn towards a resisting plane, when the angle of the two true widens; but, on the contrary, it is carried away from the plane when the angle closes: the movements are produced by the connecting-rod and the winch and to the ily-wheel. The two stamps are placed, the cus at the movable end of the lever, above the metal to be at he movable end of the lever, shows the measure we coined; the other is situated beneath, the two planes being parallel. The pieces to be coined are piled up in an iron cylindrical vessel, and at every turn of the fly-wheel the nether piece is taken away, and prised under the press, being contained within a largely, which limits its circular diameter. When the lever rises, the coin spontaneously leaves the ferrule Cylinders. The principle of this press consists in Cylinders. The principle of this press consists cylinders, having their axes parallel and turn opposite directions. These cylinders have on outer surface engraved matrices, smooth and fur ferrules, as well as ferrules with inscriptions. Fig. Plate XXXVI., presents a transversal section of machine perpendicular to the axis of the ordinal Fig. 2. Plate XXXVI., is a vertical section made throrig. 2. Plate AAAVI., is a vertical section mades this axis. The cylinder A receives the moral the moving power: its axis has length enough the case to have cogs, B, engaged into the rince the axis C. This axis has a fly-wheel, C, and can to work by any moving power through the pulses. The second cylinder (A') is constructed almost it. The second cylinder (A') is constructed almost line the first, and of equal diameter, having the same nutries of matrices. Two wheels (E, E') are connected with one of the extremities of the cylinders, in probe the they may receive motion. In the swollen control the second cylinder (A'), and on its surface, there are executations to receive the matrices (a, Eg. 3, Plate XXXVI.); they are cylindrical. Retailer disher (a sup-

Codering

or from the measurement of the optimizer. In This governed. Butterned (i), heads to make high of the matrices, are inverted, the first interest of the matrices of the street the train out, which, when affected, the futterness are sent back to their original bettien by the spring of the central part of the agent surface of the cylinder A, groves are made to resirve the ferrule matrices of the form of which braisphanael (fig 3), so that they can oscillate, through the rotary motion of the evinders. The plane surface which terminates each matrix, and which is entraved, passes through the centre of the sphere, but the outer arounference of this surface should be somewhat eccentric to the surface of the subere somewhat eccentric to the surface of the sphere Pillius can be placed within the groove under the mattices they are of steel, and can be regulated by a matters they are of steel, and can be regularly sores. The matrices are by this means secured from the catilisators Steel springs (c, fig 1) act upon the slaped edges of the terrule matrices, to force these last to the place they should occupy, as soon as they are no more opposite the matrices a A tube (F) taining the pieces about to be coined furnishes them to the matrice. The circumference or the second eylinder (A) is surrounded with steel plates (f), which have at their centre a sylindrical hole of equal diameter with the matrices a these plates serve to stimp the circumference of the con When the cylinders are placed as represented in fig 1, the lowest piece in the tube I is in contact with the surface of the plate, as soon as the matrix comes to surince of the plate, as soon as the matrix comes to the orifice of the tube, the prece falls into the vacuum formed by the plate and comes in contact with the engraved surface of the matrix. The cylinder con tinuing its rotation, brings the metal within reach of the ferrule matrix, and the coin is stamped on both sides at once. It is then pushed out of the matrice by h, assisted by the s rayer q, which has a counterpoise. The turning pieces of the cylinders are received in pillows, which allow them no lengthwise displacement, and in order that the matrices may be retained in the same plane, perpendicular to the axis of the cylinders, these are exactly clamped between the two chuck process of the cases which contain their pillows Wedges pressed by acrews (A) hold the pillows firmly fixed. The contains as they fall receive no shock, and are received in a box enclosed within J, the framework of the machine Such a machine coms more than a hundled pieces per minute, or sixty thousand pieces in a day of ten hours continual labour. The moving The moving lower required is but slight. This press performs its power required is but shight this press personnel functions without noise and is not liable to be put out of order, its construction is simple, and it requires little room. The workman who attends it is perfectly little room safe during his labour Should any acci lent or obstacle doour, the machine is so arranged that it stops apon tansonsly, the fly-wheel (C') is maintained on the axle by a species of brake (fig 2), which allows it to turn back without turning the axle, when a greater resist abose than usual is experienced by the nistrices, so that the attendant is made aware of the accident. M Beguin has put forth a proposed new method of stamping money, medals, and jewellery This consists method of stamping money, medals, and jewellery. This consists a placing within the matrices a certain number of steel stamps. These matrices being piled one upon the other, are inclosed in a rectangular box and made to place between two cylinders. This pressing is performed rapidly and many pieces are worked in a short time. The stamps are placed within the matrices, and are of a slightly coincal shape. In order that they may be retained at the same level, a strong plate covers the matrices. A thin plate is interposed between the two matrices. A thin plate is interposed between the two matrices, and is pierced with a number of holes equal implifies, and is pierced with a number of holes equal to the stamps its use is to keep the pieces to be stamped in connection with the stamps. This plate is used of steel, having its surfaces even, and an equal band in all its points. The machinery is carefully fixed in a rectangular frame, which is of iton, and hadds the different parts so firmly fixed that they are such daranged shile between the rolling cylinders. We have proposed to furthers describe the points of the resulting in the proposed to the machine. is usage of steel, having its surfaces even, and an equal fashiness in all its points. The machinery is carefully fixed in a rectangular frame, which is of non, and inside the different parts so firmly fixed that they are more proposed to further describe the points of this part of our proposed to further describe the points of this basisful machines as figured on Plate XXXV. In I is a lateral alevation of the machine. A is the principal safe, turned by a window the view proposed to the lever C the movement of the winch.

Coln (See Numishatics)

Coln (See Cocol Nut First)

Coln, loke (Ang Sax ) is the dense character maintenance.

COAP, Aoka (Ang Sax), as the dense observed imministration of the retort after coal has been submitted to destructive distillation. It consists almost emission of carbon, with an admixture of mineral matter. As police contains so large an amount of carbonassous matter, it is particularly valuable where an intense seat without smoke as required. It is therefore much simply and for smelting furnaces, but its clef use is as is second-tive fucl, and it is made for this purpose in energous quantities by the different railway companies. quantities by the different railway companies. The simplest way of coking coal is to burn the inter material in large heaps in the open air, downing them with ashes and earth to prevent combustion taking place too rapidly, but this method was found to take up a great deal of space, and experiments proved that the resulting coke was not so dense or valuable as when a coking own was applied. a coking oven was employed. These ovens are generally ranged in rows of one hundred or more, a railway pany ranged in rows of one hundred or mayer, ranking being laid along their roofs for the entrepance of the coal and withdrawal of the coke. The heat has to be regulated carfully during the process, which takes to thirty or forty hours. When coking is properly conducted, a very small portion of unconsumed gas and soot escapes and the coal, if good, yields 30 per sent. of compact coke

of compact coke

Coi (HICUM kol take hum (after Colema, its native country), in Bot, a gen of plants belonging to the nat ord Melanthacee The most important species is C autumole, the common meadow-passron. This is an indigenous perennial, growing in themselves. This is an indigenous perennial, growing in themselves of Hiretordshire, Worcestershire, Gloucestershire, and other countries. It blessems during the months of August and September, its flowers being croous like, and of a purple colour. Take plant offers a strange contrast to most others in the mode of producing flowers and fruit. The flowers supposed furing flowers supposed furing a strange contrast to most others in the mode of pro-ducing flowers and fruit The flowers appear during the autumnal mouths named, rising from the ground without any leaves, and, when they fade, nothing further is seen of the plant until the following spring, when tuits of leaves make their appearance, inclosing the seed-vessel or capsule, which ripers about hay-havest. Both the seeds and corms of this plant are employed medicinelly in contracting.

ing the earth that surrounds them, so as to form an open oval space; others form a ind of occors or web round them; and some samme the perfect state without any sort of preparation. Although some of these meets may be murious to vegetation, taken as a whole, there can be no doubt that their existence is conductive to man's conductive, and in some cases to a much greater extent than he suspects. Thus, the ingrebecties (Corandala, the diving-bestics (Dytacrda), the lidy-birds (Corandala), the diving-bestics (Dytacrda), the lidy-birds (Corandala), and many others, do mankind great secrete by preying upon caterpility, plant lice, for while the many dung-bootles (Copriside, Huts-the, Sootsupada, &c.), do good work as removers of tarrion and as nearengers generally. Others there are same, Geograpsian, &c ), do good work as removers of married and as accuragers generally. Others there are which sublist on the various poisonous fungi, and where, again, which attack dead but still standing the standing are the ground. The cause them to cease the causer the ground. mand of the regiment devolving on the lieuteness, calculd, who is responsible for the drill and disciplies of the corps. The term is not found in English miliof the corps. The term is not found an Anglesh mist-tary history prior to the regn of Queen Elizabeth, when colonels were appointed over regiments divided into ten companies, each commanded by a captain. It is supposed to be derived from the Latin cerosavins, which implies the act of installing an officer in the command of a corps of men, and thus teems probable, as coronal is the Spanish title for an officer of this rank

COLONIZATION. (See COLONY.)
COLONIZATION SOCIETY, kel-on s-seet-sheen, is a society in the United States of America, founded in 1816, with a view "to promote and execute a plan for colonization". nizing (with their consent) the free people of colour residing in that country, either in Africa or some other place, as Congress shall deem expedient." Shorten, place, as Congress shall deem expedient. Shormed, on the western coast of Africa, was selected as a substantial specific the colony, and in 1820 the first slap was more than 1,200 inhibitants; and subsequently it received the name of Liberia. In 1847 Liberia, with received the name of Liberia. In 1947 Liberia, with the full consent of the society, became an independent

the full consent of the society, became an undependent republic. From the foundation of the scenety down to 15 19 its receipts have been 1,390,939 dollars, and it has sent out no rely 10,000 emigrants. Colonnable, kell on-aid (Lat columns, a column), the name given in Arch to a row of columns which see pour a root projecting from the building, and sup-port a root projecting from the building itself, thus forming a portice. When a colonnade is continued round the whole of the arterior of a landding or the forming a portice. When a colonnade is continued round the whole of the exterior of a building, or the interior if it be a quadrangle with a court in the contra-tive called a persistle Colonnades are to be seen in int of the British Museum, the Italian Opena-House, Covent Garden, and round. Her Majoriy's

The stre in the Haymusket

The tre in the Haymai Ret Colonia, a possession in land, a furn, from colo I till or cultivate), originally arguilled a number of persons transferred from one country or place to another, where ha, ds were allotted to them. Dr Johnson defines to be "a body of people thawn from the mother-country to making some distinct place' It to this we add that they still retain a cortain political connection with the mother-country, t definition will be sufficiently correct. Four kinds of colonies are distinguishable—1 Such as serve to case the inhabitants of a ccurrry where the people have become too numerous to subsist conveniently together, 2 those established by vactors among a war-quished people, to keep them in awe and obedience; 3 those 1 rmed by emigrants driven by oppression from their native country to seek peace and subsidence in distant parts, 4 such as are formed solely for parposes of time. In the fast of these senses, colonization must have taken place at a very early period of the world a history, when the human race began to the world a history, when the human race the world a history, when the human race began to disperse, first though the various regions of the East, and afternaids through the more remote parts of the globe likese, however, were not strictly colonists, in the sense in which the word is now used, for the parent country had no control over the settlers, and afforded them no protection. The Phenmonia were the eathert people that we have an account of conding out coloures. In their commercial enterprises they established colours in Cyprus, Crete, Sieil, and other relands of the Mediterranean, and on the coast of Spain The Greeks were early prompted to colonisation by the narrow limits of their territory, and they established communities in Asia Minor and the islands and coasts of the Mediterranean Still, though these communities were in close connection with the parent states, they were not strictly colonies in the modern ecuse of the term. The Romans were the flist people to organize a system of colonization under which the colonists still remained subject to the central power. The earlier Roman colonies were formed by establishneg bodies of Roman colonies were formed by examin-ing bodies of Roman citzens in place taken in war, who exercised ambority over the vanquished, and kept them in subjection to the Roman power. Colo-mes were the outpost of the empire, the means by which the Latin language and civilization were unpressed on subject peoples According to Serving.

place, furnished with dwellings given to them under certain conditions and regulations." They are sent out by a decree of the state, or with the general consent of the people. "Those who lears without such a consent, but in consequence of civil dissensions, are not colonies." The Romans had two kinds of colonies, but in consequence of civil dissensions, are not colonies. The Romans had two kinds of colonies, but he Roman and the Latin. The inhabitants of the former had nearly all the rights of Roman cilizens, except suffrage, and observed the laws, religion, said feativals of Roma. The Latin colonists, on the other hand, though subject to the supremacy of Rome, formed a season at cousti-Rome, formed a separate state, and possessed a consti-tution of their own. They did not enjoy the rights of citizenship, and in war served not in the legions, but among the suxiliaries. There were also military colos which consisted of soldiers to whom land was given, Instead of pay and provisions, after their campaigns. In modern times the states of Genoa and Vonce were the first to turn their attention to colonization. The colonial establishments of the Genoese were commercial, similar to those of the ancient Phonicians. They were governed by consuls sent from Genoa, and the order and justice of their administration have been much extolled. The Venetian colonization was of a more military character, like that of Rome. They sought conquest and do-minion, and ruled over the earlier inhabitants of the minon, and ruled over the earlier innabitants of the countries. Portuguese colonization much resembled the Venetian, establishing military despotisms to centralize the native trade. As Portugal declined in colonial power, Spain rose into entinence,—mainly in consequence of the discovery of the New World. Their settlements were essentially military. Gold and silver were the main objects of their enterprise,—not as the legitimate proceeds of commerce, but as the spoils of force. At a later period, these settlements underwent modification toward a commercial character. The Dutch, after establishing their independence, soon turned their attention to extending their commercial relations in foreign parts. By the early part of the 17th century they had taken, one after another, all the Portuguese settlements in the East, with the exception of Gos; and by the middle of that century their power had reached its height: their possessions under the jurisdiction of the governor of Batavia had attained the extent of an empire; and these magnificent results were accomplished by a trading company, like the English East-India Company, and managed by a board of directors in Europe. The chief object of the Dutch in colonizing was to increase and to monopolize their French colonized Canada, and, on the whole, in a humane manner; but their establishments were too much of a military character, and the civil population increased very slowly. Louisians they bought from Spain, but made little progress in it, and sold it to the United States. Their recently-acquired colony of Algeria was obtained by conquest, and has had to be maintained at a great cost of blood. The English colonies have been acquired in almost every possible variety of way,—by settlement, by conquest, by treaty. They have generally local legislatures, elected by the people, and a governor and council named by the sovereign. "The Phonician colonies were factories; the Roman colonies were garrisons; the Spanish colo mies were gold-mines worked by slaves; France justly mes were gounded to the Algerian colony in our Exhibition under the heading Ministry of War. The Greek cities, in the hour of their greatness, founded new cities the counterparts of themselves. England has had the honour—an honour which no disaster can now rend from her—of becoming the parent of new now read from her—or pecoming the parent of new mations. To colonize in this, the highest sense, is the attribute of freedom."—(The Foundation of the American Colonize, by Goldwin Smith.) There are numerous theorism questions in politics connected with this leaf which our limits do not admit of our enterpoin. Colonization has been one of the most than the great of civilization. The portant means in the spread of civilization. stion that founds a colony in an unoccupied counary, or in a country occupied only by savages, ex-tends the empire of civilization, it may be to an indefinite degree. The commercial intercourse that springs up between a mother country and her colo- of this kind in modern times is the colossal statue of nies in necessarily of great advantage to the former; Bavaria, at Munich. It represents a Titanic Virgin, 532

but after a colony has been fully established, and such a footing as to be able to maintain itself, it comes to be an important question how far it is right or proper to the mother-country to retain it is subjection. It is rarely the case that a colony yields a greater revenue than is required for its government and defence, and the deficiency must necessarily fall upon the mother-country. The total expense of her various colonies to Britain is upwards of 24,000,000 monable. annually. "If our present relation with a colony such as Jameica or Canada entails any expense on the mother-country, we may ask whether all the com-mercial advantages that result from this relation would not be equally secured if only the free commercial relation existed, and that of administration were to cease. In support of this view, it is shown that the commerce of Great Britain with the United States, now free and independent, has increased most wonder fully since the separation, and probably more rapidly than it would have increased under the colonial system. This being the case, a similar increase might be anti-cipated in the trade with all those foreign possessions. whose trade is really of any importance. (Article Colony, in English Cyclopædia.) No colonies were ever reckoned half so valuable as those which now form the United States; and it was generally supposed that their emancipation would be decisive of the fate of Britain. On the contrary, however, our trade, our wealth, our power, have been greatly increased.

COLOPHON, kol'-o-fon (Gr.), in Ribl., is applied to the conclusion on the last page of an early-printed book, where the printer's name, place, date, &c., were inserted, before the introduction of title-pages. It is taken from the Greek proverly "to put a Colophon to famous cavalry of Colophon, an Ionian city of Asia, whose charge usually decided a battle.

COLOQUINTIDA. (See COLOCYNTH.)

Colossians, EPISTLE TO THE, ko-losk'-yanz, is one of the smaller canonical epistles of the New Testament, addressed by St. Paul to the Christiaus of Colosses, a city of Phrygia. The evidences in favour of the authenticity of this epistle are so strong, that few even of the extreme rationalists of the present day have ventured to deny it. It is generally believed to have been written by the apostle Paul from Rome about 2.D. 62. There is a very close connection between this They epistle and that addressed to the Ephesians. were both written about the same time, and the condi-tion of both churches was somewhat similar. The chief object of the apostle in this epistle was evidently to counteract certain philosophic or Judaistic doctrines that had crept into the Colossian church, and which he regarded as endangering the purity of the Christian religion. He exports them steadfastly to adhere to the doctrines which he taught, and to reject all such errors. From the allusions made to them in this epistic, we gather that in many respects they resem-bled the dreamy speculations of the Jewish Essens, moulded and extended by contact with the false philosophy which, under the form and name of Gnosticism. prevailed over the East.

prevailed over the East.

Colossus, ka-los'-sus (Lat.), a word used by the ancient Greeks and Romans to designate a statue of gigantic size. The most remarkable work of this kind was the Colossus of Rhodes, a statue of Apollo, or the Sun, which was so high that, it is said, ships in full sail could pass between its legs. It was considered one of the soven wonders of the world, and was the work of Chares, a pupil of Lysippus, who spent twelve years in making it. It was 105 Grecian feet in height; and stood with extended legs on the two moles which and stood with extended legs on the two moles which formed the entrance into the harbour. According to Pliny, it cost 300 talents, and few persons could embrace its thumb. Within was a spiral staircase, which led to the summit, whence, by means of a great mirror attached to the neck, Syria and the ships proceeding to Egypt might be seen. This famous statue was thrown down and shattered by an earthquake in B.C. 224, about iffly-six years after its erection. For 283 years the fragments lay about the base, when they were sold by the Saracens to a Jew of Enfess, who loaded 900 camels with the metal. One of the most remarkable works of this kind in modern times is the colossal statue of

majestic beauty, with a lion by her side, and et in height, standing on a granite padestal

is 54 thet in height, standing on a granite pedestal 50 feet high.

Colorya, issulting (Lat. color).—The source of all colors is light, as may readily be seen on salling to remembrance the colories and almost indistinguishments are to discuss in a toom from which the light has been mearly entirely excluded. When the light wholly shut out, all is dark, and we cannot distinguish anything in the recom; but as it is gradually re-admitted, we begin to recognize the forms of objects, all of which appear to be of a dark neutral tint, and at last, when the sun's rays, or rays of artificial light, are permitted to illumine the spartment, everything appears in its proper and neutlar colour. The pure white light of the sun can be separated by a simple experiment (see Dispersion, Raymanow, Paismario Colours) into tints which range in the following order:—red, orange, yellow, green, blue, violet, and indigo. These tints were supposed to be the primitive colours; but it is now known that light consists of rays of the three primitive colours, red, blue, and yellow, and that the others, which were originally ranked among the primitive colours, are in reality, secondary or complementary colours, formed by the union of any two of the primitive ities. Now, when the sunlight isle on any object, it either reflects or absorbs the whole of the rays of which light is composed, or it reflects some and absorbs the remainder. When the whole of the invidental light is light is composed, or it reflects some and absorbs the remainder. When the whole of the incidental light is reflected, the object, if it be unpolished, appears to be white; if all the rays are absorbed, it seems to be black; but if part of the rays are absorbed and part reflected, it appears to be of the colour of those rays that are reflected; thus, simply, if all the rays except red are absorbed, and the red rays only are reflected, the object will appear to be red; if all except the blue rays are absorbed, it will seem to be blue. All variations of colour are produced by the reflection of certain rays in combination: thus, if the surface of any object or material absorbs all the red rays, reflecting those of blue and yellow, these will form green by combination, and the article will reflect or scatter rays of a green tint, and appear of a green colour. When light, therefore, talk on any body, if it be polished, the rays are almost entirely reflected; but if its surface he without polish, and opaque, a part of the rays of which light is pouss, and opaque, a part of the rays of which light is composed are absorbed, and part reflected, which causes the surface to assume the apparent colour which it presents to our sense of sight. The perception of form, however, is caused by the endless variation of light and shadow falling ou the projecting and receding portions of any object; and when a painter represents portions of any object; and when a painter represents any person or thing on canvas or paper, he produces the appearance of roundness, angularity, and solidity, that belong to the form of the object he is gainting, by making the tint that he is using lighter for those portions on which the light falls, and darker for those that are in shadow. Thus, in representing a piece of armout formed of registed steal, the high lights which round. are in shadow. Thus, in representing a piece of armour formed of polished steel, the high lights which represent the prominent points and ridges, from which the light is reflected with the greatest brilliancy, are put in with opaque white colouring matter, while those parts which are removed from the light, or which, in parts when are removed from the ngm, or when, in other words, are in shadow, are represented by pignestis of a dark colour, or very dark shades of the normal sint which the entire surface of the object naturally exhibits. A further notice of colour connected with the fine arts will be found in the article databased to Painting (No. PINTING)

devoted to Painting. (See Painting.)
Conform Blindness is a curious defect of vision, from which the eye is incapable of distinguishing colours. It is of three kinds:—(1) An inability to colours. It is of three kinds:—(1) An inability to distinguish any colour, properly so called, the person being only able to distinguish white and black, light and shade. (2) An inability to distinguish between the primary colours, red, blue, and yellow, or between these and the secondary or tertiary hues, such as green, purple, orange, and brown. (3) Inability to distinguish nicer shades and hues, as greys and neutral tints. The first form is rare; the second and third are common. Dr. George Wilson found, that of 1,164 persons examined by him in Edinburgh, 65, or 1 in 177, were colour blind; of these 21 confounded red with green, 19 brown with green, and 25 blue with green. The colours most liable to be mistaken with

### Column

each other are,—(1) Red, fall and bright, including ormson, easylet, and the redder shades of orange, with full and bright green; (2) brown, including dull red, with dark or dull green; (3) purple, including pink, erimson, illac, lavender, and other mixtures of red and blue, with blue; (4) green with blue; (5) red, including crimson sand searlet, with black; (6) including crimson sand searlet, with black; (6) including crimson sand searlet, with the purple, of the control of all colours, such as straw-colour, &c., with white; (7) dark shades of all colours, such as sharet, purple, olive, blue, with black. Colour blindness is hereditary, and generally shows itself in more than one member of a family. The cause of it is not known, but it is generally referred to some peculiarity of structure in the retina or brain. The subject is of great practical importance, from the extent to which coloured signals are employed or railways and at sea.—Ref. Researches on Colour Blindness, by Dr. George Wilson—Edinburgh, 1855. Wilson-Edinburgh, 1855.

COLOUR PRINTING. (See POLYCHROME PRINTING.)
COLOURING MATTER, kull-ur-ing.—Most vegetable COLOURING MATTER, kww-nr-ing.—Most vegetable substances contain colouring matter that can be separated from them. Many of them are used as dystuffs. They are found in all the different organs of plants. In madder and turmeric they are found in the roots, in logwood and fustic in the wood, in quercitron in the bark, in safflow they are furnished by the authers, while in susatto and Persian berries they are obtained from the seeds. Many colouring matters are possessed of ne tintarkil. and retain nerries they are obtained from the seems.

Many colouring matters are possessed of ne tinctorial power as they exist in the plant, and it is not until they are brought into contact with some chamical agent, such as oxygen or ammonia, that they give evidence of any colorific property. Examples of these may be indicated in the cases of indigo and the lichens. colouring matters generally are destroyed by oxygen, chlorine, and sulphur, especially when these bodies act in conjunction with solar light. There are, however, exceptions to this, as some colouring matters require to be oxidized before developing any colour. Colouring matters which are capable of fixing themselves to fabrics without the intervention of any other substance, are called substantine colours; those which require a mordant are called adjective colours. The colouring matter of animal substances appears to be due in a great measure to iron. In minerals colour results from a variety of different elements,—iron, chromise, and copper appearing to play the largest part in painting the earth.

COLTSPOOT. (See TUESTLAGO.) COLUMBID E., kol-um'-bi-de (Lat. columba, a dove), a fam. of birds comprising the pigeons, doves, and turtledoves. The Columbids are chiefly remarkable for the way in which they feed their young. The bird's crop is furnished with numerous glands, which, in both sexes, become developed during incubation. These glands secrete a sort of milky substance, with which the food that present into the contract of the that passes into the crop is moistened. Saturated with this fluid, the food is regurgitated by the old birds

for the nourishment of the young. (See Pickon.).
COLUMELLIACEE, kol-u-mel-le-ai-se-e, in Bot, a small nat. ord. of dicetyledonous plants in the sub-class Corollifloræ. It consists of the single genus Columellia, which includes three species,—evergreen shruhs with opposite exstipulate leaves and unsymmetrical terminal vellow flowers. They are native of Mexico and Peru. Their properties and uses are unknown.

COLUMN, koll-um (Lat. columns, a column), in Arch., the name given to a pillar which is used to sup-nort a superincumbent weight in various ways. It port a superincumbent weight in various ways. consists of three parts, the base (see Base); the capital, which gives the distinctive character to the whole column in classic architecture (see CAPITAL); whole column in classic architecture (see CAPITAL): and the shaft, which forms the central part of the column between the capital and base. As the peculiar forms of the capitals of the five classic orders of architecture have been already noticed, it will merely be necessary here to treat of the shafts only. These were circular in form; but the external surface of columns of all orders except the Tuscan were fluted or orgamented with longitudinal grooves running from top to bottom. They are generally about twenty in unmbers and in Doric columns they are flat and shallow, and without fillets between the grooves, while columns of the remaining orders have fillets between the grooves.

538

### Column

and the grouves themselves are much deeper, having their bornsontal section in the form of a semicircle or semi-slippe. Sometimes the fluting is filled up to one-third the height from the base with casing, either plain or organisated. The Greeks and Romass out their columns in such a manner as to make them swell out slightly at the ut one-third of the entire height from the base. This was called the estate of the column, and was effected by means of a sliding rule known as the rule of Kimmedea. The measurement and proportion of solumns were regulated by the diameter of the lower and of the shaft, which was divided into two parts selfed smodles, each module being subdivided into the strictly minutes. Peculiarities in the columns used in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods will be achieved in the architecture of different countries and periods and the architecture of different countries and periods will be achieved in the architecture of different countries and periods and the architecture of different countries and periods and the architecture of different countries and periods and the architecture of different countries and periods architecture of the achieve and periods will be noticed in the articles devoted to each style of

architecture respectively (see Plate XXXVII.).—Ref. Bir W. Chambers's Architecture; Stuart's Athens. Convers.—In Mil., when a body of troops are dispeed in such a manner as to present a narrow front, leg are said to be in column. The term "in column" is diametrically opposed to that of "in line," when properresent an extended front. A division or brigade be formed in column of battalions, and a regiment or battalion in column of companies, the regiments or companies, as the case may be, being generally moved to the rear of that on the right or left flauk. In manusuring a single company, it may be formed in rotumn of subdivisions or sections; in forming close column of sections, the formation is made on the second section, or left section of the right subdivision; the first section moving to the front of it, and the third and fourth to the rear. When sections, subdivisions, companies, or regiments, forming a column, are at such a distance from each other that they can wheel into an unbroken line, they are said to be in open column; when within one-fourth of the length of either of the divisions named, they are in quarter-distance column; and when within a few paces of each other, in close column.

Coma, ko-ma (Gr. koma, from keo, I lie down), in Path., is used to denote a diseased condition of the brain, manifesting itself in a state of insensibility resembling sleep, from which the patient cannot be aroused, or only in a very partial degree. Coma may result from congestion or hæmorrbage in the brain, or from any abnormal pressure on that organ; from the agency of narcotic poisons or alcohol; from exhaus-tion arising from the loss of blood, or from the action on the blood of various morbid products generated within the system. Slight come differs but little from within the system. Slight come differs but little from profound sleep; but in complete come the patient is entirely shut off from the external world, and is quite dead to all external impressions. Medical writers distinguish several varieties of come, the chief of which are the some vigil and the come somnolentum. The former is characterised by a constant disposition to sleep, without falling into a quiet, sound, or natural slumber, accompanied by delirium, muttering, and agitation; the latter is marked by profound sleep, without the power of awakening spontaneously, and, if roused, almost immediately sinking into the same state. Any of the forms of come may come on suddenly, and Any of the forms of come may come on gra-finally, and be of short duration; sense and voluntary motion as slowly returning. When its accession is motion as slowly returning. When its accession is slow, it often commences with drowsiness or headache. The causes and characteristics of this disease being so various, its treatment must also necessarily vary : generails, the object is by means of stimulants and counter-tritients to avouse the patient to consciousness. Communities, kom-bin-of-shun, in Pol. Econ., is defined to be "an agreement or union among work-

people to effect an increase of wages, or some modification of the terms of the terms. or of the terms or conditions under which they are engaged. This is the sense in which it is commonly used, but it may also be applied to a union among masters or employers to keep up prices or keep down waves. Formerly the government considered it its to interfers largely in contracts entered into the masters and servants. In particular, severe were loosted against workmen combining together

# Combretaces

appointed to impuire into and seport upon the terms of this report, so to Gose, IV. a. 95 (198) passed, repushing all the statute and commanded against one binding of masters or of working provided a summary mode of coveration and a provided a summary mode of coveration and a provide a summary mode of coveration and a provide a summary mode of coveration and a provide of the statute of the sta combinations for that purpose. This state been found defective, another was passed the year (6 Geo. IV. c. 129), which now regulates this subject. It legalizes all meetings or agreements, either yearly in which any property of the control of t subject. It legalizes all methings or agreements, extent verbal or written, for regulating the rate of stages or hours of work; but, at the same time, it imposes a penalty of not-more than three months imprisonment, with or without hard labour, for any one using violence or threats to make a workman leave his hiring or return work unfinished, or refuse to accept wor belong to any club or contribute to a common fund. or pay any line for not belonging to a club or con-tributing to a common fund, and for using violence to make any master alter his mode of carrying on his business. At present, therefore, combinations to wages or limit the hours of labour are perfectly le if unaccompanied by threats or violence; but any attempts at intimidating or preventing masters from employing other workmen, or other workmen from taking employment, at any wages they please, are illegal. Combination has its right side and its wrong: it is right when used as a means of protection, wrong when resorted to for oppression. Strength and skill are to the poor man what stock is to the capitalist, and to hinder him from employing this attength and skill in what manner he thinks proper, without injury to his neighbour, is a plain violation of the most sacred rights of man. "A hundred or a thousand capitalists may form themselves into a company or combination, take all their measures in common, and dispose of their pro perty as they may, in their collective capacity, judge most advantageous for their interests. And why should not a hundred or a thousand labourers be allowed to do the same by their stock? Of all the varieties of property which a man can possess, the faculties of his mind and the powers of his body are most particularly his own. And to fetter him in the mode in which he is to exercise or dispose of these faculties and powers, is a manifest encroachment on the most inviolable of all rights, and can be justified only by an overwhelming necessity."—(J. R. McCulloch.) These remarks, however, apply exclusively to voluntary combinations among workmen, and are not intended to countenance, in the slightest degree, the attempts that are sometimes made by combined workmen forcibly to prevent others from working, except on the terms and conditions they have fixed for their own conduct. The wages of any set of men who enter into combination for the purpose of men who exter anto combination for the purpose of raising them, must be either below the natural and proper rate, or equal to or above that rate. In the first case, then, it would be obviously unjust and oppressive to prevent them from adopting any measures, not injurious to the rights of others, to render their claim effectual. Few masters willingly consent to raise wages, and the claim of one or a few individuals likely to be disregarded, and therefore the second of the claim of is likely to be disregarded; and, therefore, it is only when a number of them combine and act simulta-neously, that their demands are likely to be regarded. The subject of illegal combinations will be further treated under the head of Conspiracy.—Bel. Engiclopædia Britannica.

COMBINATIONS. (See STRIKES.) COMBERTACEE, kom-bre-tail-se-s, in Bot., the Myro-balan fam., a nat. ord. of dicotyledonous plants, in the sub-class Caluciflora. There are 22 genera and about 2:00 species, which are exclusively natives of the tropical parts of America, Africa, and Asia. Trees or shrubs parts of America, Aircs, and Asia. Trees or structs with exstipulate entire leaves without dots, and flowers either perfect or unisexual. In the flower we may remark a superior calyx, with a 4-5-lobed desidaous limb; petals equal in number to, and alternate with, the lobes of the calyx; stamens inserted with the petals on the calyz, generally twice as munerous as the lebes of that part, though sometimes thrice as many, and sometimes equal to them in number. The order is sometimes equal to them in number. The order is remarkable for the presence of an astringent principle, better of these encoments became so apparent that which renders the barks of some species, and the fruits and flowers of others, useful for tanning and dysing. sometimes equal to them in number.

### Combustion

Some gield excellent timber: Conduction politic of Bouth-Rastern Africa, produc regetable wax, which is called dispute to who make use of it to dress their victual MINALIA.)

Countierion, hon-bust shim (Lat. combure, I burn), a term applied to the phenomenon that takes place when shemical action is sufficiently intent to produce light and heat. Gases are sometimes divided into ngue and ness. Cases are sufficiently and the decombination in the idea conversed by such a classification is an erroneous one. Air is, taken to be a supporter of combustion, and hydrogen gas burning in it as a combustible; but if the

nymoren gas burning in it as a combustible; but if the conditions are reversed, we are obliged to alter our classification; for a jet of atmospheric air may be burnt in an atmosphere of hydrogen.

Compusation, Stortambous Human, is a subject that has from time to time given rise to a considerable amount of discussion among its believers and disbellevers. Numerous apparently well-suthenticated cases are given of this nearonance, but the difficulties of are given of this phenomenon; but the difficulties of secounting for the chemical changes involved in such a case mave caused many cumment persons to reject the whole mixther, and contend that none of the cases have been sufficiently well authenticated. On a point where doctors differ so much, we may well refrain from giving an opinion. The cause to which it is usually traced is gross intemperance. The victim is almost invariably a woman, fat, and rarely under 60 years of age. The flame is described as of a bluish colour, obscure in the light, and extinguished with difficulty by water. Some times the body is said to have been consumed so as to crumble to pieces when moved, without the clothes being burned; in other cases the combustion has ex-tended to neighbouring objects. The ashes are always a fatty kind of soot; and a similar greasy matter, of feetid odour, is deposited on objects around.

COMPUTION TUBE, a tube of hard German glass drawn out to a point at one end, and used for calcining organic matter in organic analyses.

COMPUT, kom'e-de, (Gr. kome, a village, and ode, a song), is applied to one of the two kinds of dramatic rooters; and is an annual because analysis. a song, is applied to one of the two kinds of tramater poetry, and is so named because anciently sung at village festivals, by rustic actors. The object of comedy is to expose to censure and ridicule the follies and rices of mankind. It naturally divides itself into two kinds,—comedy of character and comedy of intrigue. In the former the display of some peculiar character is chiefly simed at; and the action is contrived with a view to this end, and is treated as subordinate to it. In the latter the plot or action of the play is made the principal object. The Freuch comedies are chiefly comedies of character, the English mostly comedies of latrigue. In good comedy both characteristics should be properly mixed together. In comedy, the incidents and language approach nearly to those of ordinary life, and the termination of its intrigue is happy. The ancient comedy consisted in direct and avoyed satire against particular known persons, who were brought upon the

Stage by name.

COURT, kom'et (Gr. kometes, from kome, hair), in
Astron., the name given to luminous celestial bodies which occasionally appear in the beavens, consisting of a round body, termed the head, to which a long stream a round hody, termed the head, to which a long stream of light is generally appended, called the tail, which stretches across the heavens for some considerable distance. The head consists, for the most part, of an ill-defined luminous haze, with a bright mass of light in the scatter, called the nucleus, which resembles a star or small planet in apparent size and appearance. The tail is a long train of light, streaming out like hair behind the head, whence the name comet. In some comets, the head is without any nucleus whatever, and others have the luminous head without any tail ap-

### Comet

iumitious tail, slightly curved in shape, which traffs behind the head. They were supposed by the assistent to progressionts some disastrons event, and they were considered to be within the region of the atmosphere that surrounds the sastit. Tycho Bruke proved, however, that they were storted beyond the meth sorbit, and Newton showed that they traveled in elliptical orbits of great eccentricity, the curvature of which did not differ much from that of a parabols. Considering this to be the case, and assuming the path of the comet of 1682 to be parabolic in form, the astronomer Halley calculated its orbit from Newton's observations, and predicted its reappearance about the end of 1755 or calculated its respectance about the end of 1758 are the early part of 1758, making allowances for the disturbing action of the planet Jupiter. Halley's pradiction was verified. When it reappeared, it was first observed on Christmas-day, 1758, by a German astronomer, and it passed its perihelion in Marck, 1758, thus adding to Halley's fame as an astronomer, and confirming the theory that Newton had advanced respecting the revolution of these bodies. This comet, now known as Halley's comet, which had been noticed in 1378, 1458, 1531, 1607, 1632, and 1759, appeared again in 1335, and, assuming seventy-six wars to be the mean in 1378, 1456, 1531, 1607, 1682, and 1759, appeared again in 1355, and, assuming seventy-six years to be the mean time that clapses between its successive appearance at its perihelion, it will be seen again in 1311. A description of the principal comets that are known to return to their perihelion at fixed periods, will be found closewhere (see Bittal's Court, Excest's Courts), as well as an account of the great counct of 1858. Well as an account of the great comet of 1858. [See DONAIT'S COMEN.] The comets of Faye, Because, and D'Arrest, discovered in 1843, 1846, and 1851, respectively, have also reappeared at the time calculated for their return to their perihelion. The large and brilliant comet of 1880, which is supposed to be the one that appeared in the year 44 B.C., just before the death of Julius Casar, and from which Newton derived the data which led him to assert that comets revolved from the sun in elliptic or parabolic orbits, was made round the sun in elliptic or parabolic orbits, was one of the most remarkable that has ever been observed. It presented an appearance of surpassing spleadour; its tail appeared to extend over an arc of 90°, and it approached nearer to the sun than any that have yet been noticed, except the comet of 1843, which is also considered to have surpassed it in magnificence and lustre. It is beyond the bounds of possibility to state how many comets there are revolving round the sup. which is the centre of our solar system; but it may be said that more than two hundred have been observed up to the present time, the orbits of which have been calculated. Of these, about fifty revolve in elliptic orbits, and six at least have been observed as neveral successive appearances at their perihelion. With respect to their dimensions, it was ascertained by micrometric measurement that the great comet of 1811. which is supposed to arrive at its perihelion about once in 3,000 years, had a head 1,270,000 miles in dismeter, with a nucleus in the centre, the diameter of which was about 2,640 miles, and a tail 100,000,000 miles in length. The nucleus of Donati's conset was 800 miles in diameter, while the diameter of the sur-rounding nebulous haze was about 100,000 miles, and the tail, 51,000,000 miles at its greatest length. It is not known of what substance comets consist: but it is evident that, whatever it may be, it must be ex-tremely thin, and without any sensible weight, as stars have been observed shining through comets with un-diminished lustre, which a slight fog would altogether hide from view. Newton considered the nucleus of a hide from view. Newton considered the nucleus of a comet to be a solid body; but no astronomer has ever yet observed the passage of the nucleus of any comet over a star, which would decide the question whether behind the head, whence the name comet. In some comets, the head is without any nucleus whatever, and others have the luminous head without any tail appended to it. The tail is often of great length; that of the comet of 1853, whence it is often of great length; that of the comet of 1852, called Donalt's comet, being about 50,000,000 miles in length, while that of the comet of 1853, one of the most brilliant ever observed, was quite three simes as long. These bodies travel round the sun it is supposed to be formed by a repulsive sun in the path of an ellipse, having the sun as one of the foci, or in a parabolic curve. They are only seem, when they are at their perihelion, and the tail is always the same as the sun. Comets diller considerably the sun as one of the comet of th

# Comfrey

COMPREY. (See STREETSTEE)

COMPREY, tom-ist go (Lat. se, one, or con, with, and see, to go).—Comitium is the piece of meeting, and comitie the people itself, or the assembled meeting. In the Roman constitution the comitie were the ordinary legal meetings or assemblies of the people, and statust from the concions and constitu. Comitie were those assemblies convened by a magistrate for the purpose of putting say, subject to their vote. There were various kinds of comitie:—the comitie calata, which meet on the Capitol in front of the Curia Calabra, where the people assembled acted only a passive part, where the people assembled acted only a passive part. where the people assembled acted only a passive part, historical to what was appounced, and witnessed what was peformed. The comitia curinta, where the people present had to decide by their votes whether the measures brought before them should be adopted or re-jected. The main points to be decided were the elec-tion of the magistrates, including the king himself, the jected. possing of laws, peace and war, and the capital punishment of Roman citizens.—The comitia centuriata, which endeavoured to unite the various elements of which the Roman people consisted into one great political body, in which power and influence were to be deter-mined by property and age. For this purpose Servius Tullius divided the whole body of Roman citizens into x property classes and 193 centuris or votes; from which the assemblies in which the people gave their rotes were called comitia centuriata.—The comitia tributa, which were also called into existence by the constitution of Servius Tullius, who dividence the Roman territory into thirty local tribes. These divisions, which were originally a purely topographical arrange-ment, became in course of time a formidable political power.—Ref. Smith's Dictionary of Greek and Roman Antiquities.

COMITY OF NATIONS, kom'e-te (Lat. comitas gentium, courtes of nations), is a phrase expressing the true toundation of the recognition and effect sometimes given to the laws and institutions of one country within the territories of another. It is derived altogether from the voluntary consent of the latter, and is inadmissible when contrary to its known policy or prejudicial to its interests. In the silence of any positive rule, affirming, denying, or restraining the operation of foreign laws, courts of justice presume the tacit adoption of them by their own government, unless they are repugnant to its policy or prejudicial to its interests.—Ref. Story's Conflict of Lusse.

COMMA, kom-mi, in Punctuation, is a mark thus ()

used to separate those parts of a sentence which, though very closely connected in sense and construction, require a pause between them. It represents the shortest pause in a sentence. (See Punctuation.)

COMMANDER, kom-man'-der (Fr.), the term employed

to designate an officer in the royal navy who holds

COMMANDER-IN-CHIEF, the designation of the generai officer who has the control of the entire military force of Great Britain and Ireland. He generally holds the rank of field-marshal. His head-quarters, whence all orders emanate, are at the Horse Guards, Whitehall. The office is held at present (1862) by H.R.H. the duke of Cambridge.

COMMANDERY, kom-man'-der-e, in the Middle Ages, was a kind of benefice or fixed revenue attached to certain orders of chivalry, and conferred upon aged knights who had rendered worthy services to the order or the state. Commanderies were of different kinds mong the different orders; and, after the system of nefices was abolished, the title was still retained, and conferred as an honorary dignity, as in the present day the second rank of the order of knights of the Bath are termed knights commanders. At the time of the suppression of the religious houses under Henry VIII, there were at least filty commanderies, or preceptories, as they were often called, in England.

Commander (Rr.) is a kind of commercial society or partnership, in which one or more of the members constribute a pertnership, in which one or more of the members constribute a pertain amount of capital without taking constrouse a corcast amount or capital without taking any part is the management, becoming what we call eleping partners. Such partners are called in France commandates; or partners in commandite, and are held liable for lossed only to the extent of the funds or capital farmished by them. 536

# Commerce

COMMENTACER, com-mel-s not-se-s (after J G. Commelin, colebrated Dutch betweensts), in to Commelin, celebrated Dutch betenists), in 18st, the Spider-wort fam., a nat. ord. of monocotyledonous plants, in the sub-cise Petuloiden. There are sixteen geners, which include 260 species, chiefly natives of India, Africa, Australia, and the West Indias. They have flattesed, narrow, and usually sheathing leaves. The perianth is inferior, more or less irregular, in six parts, arranged in two whorls; the outer parts being green, persistent, and opposite to the carnels. The green, persistent, and opposite to the carpels; the inner petaloid. There are six or three stamens by: gynous, some being generally abortive: their proper-ties are unimportant. The rhizomes of some species, as Commetyna tuberosa, angustifolia, and striato, con-tuin much starch, and in a cooked state are edible. Some species have been reputed astringent and rulnerary, and others emmenagogue.

COMMENDAM, kom-men'-dam (Lat.), in Eccl. Law, was originally applied to a benefice which, during voidance, was committed to the care of a person who discharged the spiritual duties, but had nothing to do with the emoluments. Such a person was said to hold it in commendam. In time, however, the restriction as to interfering with the profits came to be evaded; and this came to be adopted as a mode of enjoying pluralities. By the law of England no benefice could be held in commendam without a license from the crown; and sometimes elergymen promoted to bishopries wan an-sulficient revenues were allowed in this way to retain their benefices; but by 6 & 7 Will, IV. c. 77, it is pro-vided that no ecclesiasteal dignity, office, or benefice shall be held in commendam by any bishop unless he shall have held the same when the act passed. sometimes clergymen promoted to bishoprics with in-

COMMENTARY, kom'-men-tur-e (Lat. comminiscor, I call to mind), is a term used in literature in various significations. Originally it was applied to remarks or memoranda made on events and occurrences as they happened; as the Commentaries of Casar. At present it is usually applied to a series of critical notes and observations upon a book, either in the form of detached notes, or as a connected series of remarks, other-

wise called a running commentary.

COMMERCE, kom'-mers, is derived from the Lat. commutatio mercium, and, in its most general sense, denotes the exchange of articles of any kind for money or other articles. The origin of commerce is coeval with the articles. The origin of commerce is coveral with the termation of society, and at first must necessarily have been carried on by barter. Individuals having more of any article than they required would endeavour to find out others in want of it, and, at the same time, possessing something which they would like to have. As the population of a place increased, commerce necessarily became more extended, and various facilities for currying it on would be introduced. In the transaction between Abraham and Enheron, we read transaction between Abraham and Ephron, we read that the former paid to the latter "four hundred shekels of silver current money with the merchant" for the cave of Machpelah; and Joseph was sold to a company of Ishmacitish merchantmen travelling to Egypt with spices and myrrh, for twenty pieces of silver. These are the earliest written notices that we possess of commercial infercourse, and they show that, even at that early period, it was in an advanced state. The Phoe nicians were, however, the first nation of antiquity that seem to have devoted themselves in any great degree to commercial pursuits, and they were the first that made any great progress in navigation. They are mentioned as great traders in Genesis and in Homer; and in the 6th century n.c. their commerce embraced the entire known world, from India and Eastern Africa, on the one side, to Western Africa and Northern Europe on the other. The city of Tree was than the defining of Tree was then the defining of the city of Tree was then the defining of the city of Tree was then the defining of the city of Tree was then the defining of the city of Tree was then the defining of the city of Tree was then the defining of the city of the cit on the other. The city of Tyre was then the com-mercial mart of the world. The Carthaginians were nerval mart of the world. The Cartangians were Phoenicians by origin, and their commerce was of the most wide-spread character, especially after the destruction of Tyre. The Greeks, too, at an early period, showed considerable skill in commerce, and some of their states found in it the source of much opulence. their states found in it the source of mass optilence.
Athens was the chief commercial city of Greece, and
was as distinguished for trade as it was for art and
letters. In navigation the Romans at no time were
remarkable; but after the fall of the Roman empire
there sprang up in the north of Italy certain cities
that for several centuries kept in their bands the commerce of the world. The chief of these were Venice,

Pice, and Genos, though several others rose to son-siderable importance. In the latter part of the 15th century, Venetian commerce was co-extensive with the then known world. About the middle of the 18th century there was formed in the north of Europe an association of commercial towns that occupies an important place in commercial history. This was what is termed the Hanscatio League, and it originated at Lubeck. At first it consisted of Lubeck, Hamburg, and Brunswick; but afterwards came to include up-wards of sixty towns; among which were Dantzic, wards of sixty towns; among which were Dantzle, Stettin, Königsberg, Riga, Amsterdam, Cologue, &c. This body continued in a state of union for three centuries, after which it was gradually dissolved, the only remains of it that still exist being Hamburg, Dubeck, and Bremen. The maritime enterprises of Portugal began about the commencement of the 15th centery; while the discovery of America, at a later period, placed Spain in the first rank among maritime In the 16th and 17th centuries the lead in nations. commerce was taken in a remarkable degree by the Dutch, and in the 18th by the English. The trade and navigation of England, unexampled as it now is for extent, did not by any means make an early figure in the commercial history of Europe. This is principally to be attributed to the political struggles in which she was from time to time engaged; and it was not till after the close of the 17th century, when the country had become settled, that she began to make those great strides in commercial progress that speedily brought her to the first place. Her home industry has fed her commerce, and each has contributed to raise her to her present state of greatness. Our limits do not admit of our considering in detail this remarkable progress; but we shall attempt to give some of the more prominent features. In the beginning of the 18th century the mercantile navy of England amounted to 270,000 tons; in the middle it exceeded 600,000; and in the end it approached 1,600,000 tons; while, in 1860, the total number of vessels belonging to Great Britain and her colonies was 38,501, and their tonnage amounted to 5,710,908 tons, of which 2,337 vessels and 500,144 tons were steam. A like surprising increase hus taken place in our manufactures since the middle of the last century, occasioned in great measure by the discoveries of Arkwright, Watt, and others. The war with America, which terminated in the peace of 1783, exercised for the time an injurious effect upon our commerce; but after the peace it rapidly increased. In 1786 a commercial treaty with France was concluded, which, however, was put an end to by the war of 1793. For the first few years of the war, its injurious effects upon our trade were very manifest; but the extended circulation of bank paper in 1797 seemed for the time to bring a yearly addition to our national wealth, and this bring a yearly addition to curnational weatin, and this delusive state of matters continued during the greater part of the war. Its effects, however, began to be felt as soon as peace was concluded, and the sufferings of the succeeding twenty years were mainly owing to this circumstance. The year 1816 was among the most gloomy in our commercial history. In 1817 and 1818 a slight revival took place, but it was succeeded by a long depression. In 1822 various relaxations were made in our navigation laws, and, in 1823, trade again resived. Since that time our commercial becomes in Since that time our commercial prosperity has rapidly increased, notwithstanding several inter-ruptions that have taken place, as in 1825, 1847, and 1858. In 1845 Sir Robert Peel abolished the customs duties on 420 different articles, a measure which was followed shortly after by the total repeal of the corn laws. These measures were followed by the repeal of laws. These measures were followed by the repeal of the navigation laws in 1850. Since that time the policy pursued by the government has been more and more to withdraw the restrictions on commerce, particularly in the way of simplifying the tariff, and cutting of a number of articles that produced little revenue to the state. (See TRIFF.) The recent commercial treaty with France will doubtless have a very beneficial state of the transport of the product of the state o treaty with France will doubtless have a very beneficial active matters.

a time in operation to enable one to judge, with any dagree of accuracy, as to its results. There are three tinds of commerce:—I. Home trude, or that carried on between individuals of the same country; 2. foreign trade, or that carried on parchiment, and addressed to the officer who have that carried on between the inhabitants of the same countries; and 3. colonial trade, or that farried countries; and 3. colonial trade, or that carried to the said commission," which he is called on to dis-

carried on between the inhabitants of any particular country, and its colonists. It is impossible to form an estimate of that amount or value of the form trade of this country; but in 1886 the real value of the exports to foreign countries, of British foreign, and colonial produce, was £238,806,809.14 British possessions, £198,927,785: and the imports in the same year, into the United Kingdom from foreign countries was £298,093,503, and from British possessions, £72,206,838. It would be difficult to overstimate the advantages of commerce to the individual estimate the advantages of commerce to the individual or to society. Without commerce, man could in few or to society. Without commerce, man could in few positions supply himself with more than a few of the necessaries of life; by means of it, all parts of the world come to minister to his enjoyment; and he beworld come to minister to his enjoyment; and he be-comes in reality a "citizen of the world." In the worlds of Addison, by means of commerce, "our tables are stored with spices, and oils, and wines; our rooms are filled with pyramids of China, and adorned with the workmanship of Japan; our morning's draught comes to us from the remotest corners of the earth; wo repair our bodies by the drugs of America, and repose ourselves under Indian canopies." "The vineyards of France are our gardens, the Spice Islands our hotbeds, the Persians our silk-weavers, and the Chinese our potters." Commerce distributes the gifts of nature, potters." balancing the deficiencies of one country with what is balancing the denciencies of one country what is superfluous in another; creates a demand for labour; finds employment for wealth; and multiplies end cheapens the productions of every country. In a commercial point of view, the whole world is, or ought to be, regarded as one people,—one nation, and their intercourse as free and unrestricted as possible. The loss of a trade with one nation is so much of the trade of the wealt greening and both. of the world rescinded and lost.

COMMINATION, kom-min-ai'-shun (Lat. comminatio), is a threat or denunciation of vengeance. In the Liturgy of the Church of England it is an office appointed to be read on the first day of Lent, or Ash-Wednesday, in room of the ceremony in the Church of Bone of apprinking ashes on the head on that day. It is ensured the control of the ceremony in the Church of Bone of the Church of the Church of Bone of the Church of sprinking askes on the head on that day. Its en-titled "A commination or denouncing of God's anger and judgment against sinners;" and may be used "at other times, as the ordinary shall direct." COMMISSAHAT, kom-mis-sail-rad, a term taken from an old French word, and applied to a body of men

under the immediate command of a commissary-general or assistant commissary-general, who are at-tached to an army in the field, for the purpose of providing the necessary stores and provisions for the

soldiers. COMMISSARY, kom'-mis-nir-e (Fr. commissaire), one who is appointed or commissioned to execute some duty on behalf of another. The commissary of a bishop is an officer delegated by him to hold an inquiry or commissarial court in some distant part of the chooses; his powers are similar to those of the chancellor of the diocese, who sits in the consisterial court. In Mil. the term is applied to officers holding various positions, and oxercising different offices. There is a commissary general, who is the chief of the commissariat depart. ment, and commissaries, who inspect the muster-rolls returned by the commanding officers of regiments, and make periodical reports of the numerical strength of the army; there are also others who have to inspect the horses used by the cavalry and artillery, and who have charge of the stores under the control of the

Roard of Ordnance. COMMISSARY COURT, in Scotland, was a court estab-lished in Edinburgh, at the time of the Reformation, for the trial of such cases as had formerly come within ior the trial of such cases as had formerly come within the jurisdiction of the bishops. Its powers were from time to time diminished, until it was entirely abelished in 1836, and its powers transferred to the Court of Session. At present there is what is called a commissary court in each county, of which the sheriff is commissary; but its jurisdiction is limited to decreaing and confirming executors to deceased persons and

# Commission

charge, in virtue of the rank he holds in the regiment or corps to which he is appointed. Commissions of efficiers in the army are signed by the queen; those of officers in the army are signed by the queen; those of officers in the rary, by the first lord of the Admiralty; and those of volunteer officers, by the lord-lieutenant of the county in which the corps to which they belong have been raised. In the taxy, engineers, artillery, and marines, officers obtain their commissions without purchase; but in the cavalry and infantry, gentlemen obtain commissions as ensigns and cornets by purchase, and ries to higher grades successively, by paying the difference between the price of the commission of the rank they are about to enter, and that of the rank they are about to enter, and that of the rank they are about to enter, and that of the rank they are about to enter, and that of the rank they are about to enter, and that of the rank they are adout to enter, and that of the rank they are about to leave. Commissions are sometimes given as rewards to meritorious officers, and considerable time, with honour and distinction. Cadets who have studied and passed at Sandhurst also obtain commissions without purchase, and the commander-in-chief can grant the same to some of deceased officers, or in any case which appears to him to require it. Of the undermentioned commissioned officers in the army, the colonel, lieutenant, engineerial officers; and the chaplain, adjutant, quartermaster, and surgeon, staff officers. The prices of commissions in various branches of the army are as follows:—

Rank. Foot-Grds.	Life (1) & H. Guards (2).	Drags.	Inf.
Lieut Colonel £9,000	£7,250	£6,175	£4,500
Major 8,300	5,350	4,575	3,200
Captain 4,800	3,500	3,225	1,800
Lieutenant 2,050	$\{1,785 (1) \}$ $\{1,600 (2) \}$	1,190	1,100
Cornet, or 1,200	$\{ \substack{1,269\ (1)\ 1,200\ (2)} \}$	840	450

Every particular with regard to the full-pay and halfpay of officers of all grades in the army, navy, and marines, will be found in Hart's Army List, and Marray's Navy List.

Conjussion, the warrant or letters patent which all men exercising jurisdiction, either ordinary or extraordinary, have to authorize them to inquire into, hear, or determine any cause, action, or matter; as the consistion of the judges, justices of the peace, &c.—Commission of the judges, justices of the peace, &c.—Commission of Lunacy, a commission issued out of Chancery to inquire whether a person represented to be a lunatic be so or not.—Commission of the Peace. Justices of the peace are appointed by the queen's special commission under the great seal, the form of which was settled by all the judges in 1590: this appoints them all jointly and separately to keep the peace, and any two or more of them to inquire of and determine felonies and other misdemeanours. Stipendiary magistrates, specially appointed for the metropolitan and other districts, have the power to act singly, and with the same jurisdiction and power as two or more justices of the neace.

Convisionable, kom-mis-thun-air' (Fr. commistionsire, one who is appointed to execute some office),
the name given to the members of a corps who have
been enrolled since the termination of the Crimean
was, to furnish the public with trustworthy messengers
who will execute any commission on receipt of a cortain sum fixed as a remuneration for their services.
Most of them have served in the army, and are incapacitated, for other employment by the loss of an arm
or a legisThey wear a military dress of dark green,
with a black leather waist-belt, cross-belt, and ponch.
The corps possesses an excellent band. Their barracks
are in Exchange-court, Strand, but there are stations
in many of the great thoroughfares, where they may be
found waiting for employment.

Cormissues for mish'-are (Lat. commissura, a joining

Correspond to temporal the commission as joining together; is a joint or seam, the place where two hodies or parts of a body meet and unite. (See

Committee, kom-mil'-te (Fr. comité), a certain number of persons elected or appointed from a more numerous body to perform some special act or investiration. Although a committee does not usually consist of less than three members, it may be formed of one and member only. On the other hand, the whole of 538

### Common

the members of a body may be resolved into a committee; as, for instance, when all the members of the House of Commons form themselves into a "committee of the whole house." When this latter proceeding takes place, the speaker vacates the chair, being superseded by a paid official, denominated the chairman of committee. In a similar way the chancellor of the House of Lords leaves the chair, which is then occupied by the chairman of committee of the upper house of the legislature. (See Parliament)

house of the legislature. (See Parliament.)
Committee or Public Safety (Fr. Comité de Malus publique) was the term applied to a number of members of the National Convention during the reign of terror, 1793-4, who acted as the dictators of Frayes. The committee arose out of that section of the Convention called the "Mountain," which had gained the victory over the Gironde party; and at length its power came to be concentrated in three of its members.—Robespierre, the real chief, though half-concealed from view, Couthon, and St. Just. Among these men there was perfect equanimity down to the moment of their fall; and there is reason to believe that they had resolved to perpetuate their power by that they had resolved to perpetuate their power by establishing a supreme council of three consuls, in which Robespierre would have had the perpotual presidency, with the departments of justice, exterior, and finance; Couthon that of the interior, and St. Just the war department. The career of this sanguinary tribunal was brought to a termination by some of their former associates unpeaching its members before the Convention; and a reaction having taken place in the public mind, Robespierre, Couthon, and St. Just were executed on the 5th Thermidor (July 28, 1794).—

Ref. Cartyle's French Revolution.

COMMITMENT, kom-mit'-ment (Lat. committo, I commit). is the ordering into custody an offender, or supposed offender, in order that he may be committed to prison to answer the offence. For criminal offences he may be arrested by,—1. warrant; 2. by an officer without warrant; 3. by a private person, also without warrant; 4. by hue and cry. In either case he must be taken before a magistrate to be dealt with, who, upon sufficient cause, issues his warrant of committal. A committal may also be made by a court of record for contempt for not obeying its order (in cases where a judgment cannot be entered) to pay costs, a fine, or other moneys, or otherwise in disobeying its mandate, Or it may be by the court ordering a person into the court, in the body of the court or its precincts, abasing its process and otherwise, or for not patting in bail in cases where bail is requisite. And cach of the houses of parliament may, by warrant, commit a person for contempt of its power or authority, or a breach of its privileges.

COMNUDER, kom-mo-dore' (Span. commendador, a commander), the designation of an officer in the navy who has the command of a small number of ships separated from the fleet for any special service. The office is held by a captain, who ranks with a brigadier-general in the army. There are two classes of commodores in our navy: those of the first class carry a red pendant, broad and swallow-tailed, at the mast-head; those of the second, a blue pendant. Commodores rank in the navy next to a rear-admiral.

COMMON, kom'-mon (Lat. communis, Fr. commun), or right of common, is an incorporeal hereditament, and a profit which a man has in the land of another; as, to feed his beasts, to catch fish, to dig turf, to cut wood, or the like. It derives its name from the community of interest which thence arises between the claimant and the owner of the soil, or between the claimant and other commoners entitled to the same right, all which persons are entitled to bring actions for injuries done to their respective interests; and both as against strangers and against each other. Common is chiefly of four sorts:—A. Common of pasture.—This is the right of feeding one's beasts in another's land, and it is either appendant, appurtenant, because of vicinage, or is gross. Common of pasture appendant is the privilege belonging to the owners or occupiers of arable land held of a manor, to put upon the wastes of the manor (thence called commons) their commonsible beasts; that is, such beasts as are necessary either for the ploughing of land or for its manuring; viz, horses and ozen, cows and

### Commonalty

b. It can be claimed only in respect of arable though it may be claimed by that name as appendant to a farm in fact containing pasture at the present day, for the land shall be presumed (where there is usage to sustain the claim) to have been all originally arable. Common appartenant (which is all to be frequently confounded with common appendant) so be frequency contounded with common appendent) arises from no connection of tenure, nor from any absolute necessity, but may be annexed to lands in other lordships, or extend to other beasts besides such as are concraity commonable: as hogs, goats, geese, or the like. It can only be claimed by grant, or by the long usage of particular persons to enjoy the same; which latter title is commonly called a title by prescription, and is supposed by the law to be founded on a special grant or a greement originally made for this purpose, Common because of vicinage, or neighbourhood, is where the inhabitants of two townships which lie contiguous to each other have usually intercommoned th one another, the beasts of the one straying naturally into the others' fields without any molestation from either. Common in gross, or at large, is such as is neither appendant nor appurtenant to land, but is annexed to a mansion, being granted to a man and his heirs by deed; or it may be claimed by prescriptive right, as by a parson of a church, or the like corporation sole. This is a separate inheritance, entirely distinct from any other landed property vested in the person to whom the common right belongs. 2, 3. Common of piscary is a liberty of fishing in another man's water, as common of turbary is a liberty of digging turf upon another man's ground. There is also a common of digging for coals, minerals, stones, or the like. Common of turbary may be by grant or prescription, and may be either appurement or in gross. A common of turbary cannot be claimed as appurement to land, but only to a house, and does not authorize the taking of turf, except for the purpose of using it as feel in the particular house to which the claim of the control of the purpose of the pu right is anuexed. Common of estovers or estouviers, that is, necessaries (from esloffer, to furnish), is a liberty of taking necessary wood, for the use or fur-niture of a house or farm, from oil another man's estate. (See BOTH.)

COMMONALTY, kom'-mon-al-te, is the lower of the two divisions of the civil state, the nobility being the other. Like the latter, it includes several degrees of rank and

condition.

condition.

Common Bench. (See Court.)

Common Council, is the council of a city or corporate town, empowered to make bylaws for the government of the citizens. The common council of London consists of two houses,—the upper house, composed of the lord mayor and aldermen; and the lower house, of the common conneilmen, elected by the several wards. The members of the common council are elected annually by the ratepayers of the different

COMMONER, kom'-mon-er, is a student of the second rank at the universities of Oxford and Cambridge.

COMMON LAW.—The common law is grounded on the general customs of the realm, and includes in it the law of nature, the law of God, the principles and maxims of the law, and the decisions of the superior courts, which are founded thereon; and is said to be the perfection of reason, acquired by long study, observation, and experience, and refined by learned men in all ages. It overrides the canon and civil law, where all ages. It overrides the canon and civil law, where they go beyond, or are inconsistent with it, as we have ady noted in considering those subject

already noted in considering those subjects.

Common-Place Book, is a book in which are recorded and arranged under general heads such things
as may occur in the course of reading or study, in such
a way as that they may be easily found again. The
advantage of such a book to the student or man of letters is very great. It not only trains him to read with accuracy and attention, but leads him insensibly to think for himself, and to watch over his own thoughts, To most reflective men there occur at times valuable thoughts, which, without some such way of preserving them, are generally lost. The method of arrangement adopted in a common-place book is of some importance, and various plans have been proposed, each having its dvantages. The best is, perhaps, that which is given by Mr. Locke, and which, from twenty years' experi-

# Common-place Book

ence, he found of the greatest advantage. The method recommended by him is briefly as follows:—The first page, or, for more room, the first two pages that fronteach other, are to be made to serve as an index to the book, and to contain references to every pince or matter therein. These are divided by parallel lines into twenty-five equal parts, whereof every fifth line is to be distinguished by its colour, or some other circumstance. These lines are to be out perpendicularly by others drawn from top to bottom, and in the several spaces thereof the several letters of the aiphabet, botta capital and minuscule, are to be written. The manner capital and minuscule, are to be written. The manner in which this is done may be best seen from the following example of the first four letters :

A	a	О	a
	•		e
	i		<b>i</b> (1)
	0		0
	и		u
в	а		æ
	в		в
	i	D	<b>i</b>
	0		0
	u		u

Having fixed upon the head to which the thing to be entered may be most naturally referred, we regard first the initial letter, and then the first vowel that follows it. For instance, in Beauty, B is the initial letter and e the first vowel; we look in the index for the partition B and the line e, which is the place for all words whose first letter is B and first vowel e; and finding no numbers already down to direct us to any page of the book. we turn forward to the first blank page, which, in the case of a new book, will be page 2, and there write what we have occasion for on the head of heauty; beginning the head in the margin and indenting all the other sub sequent lines, that the head may stand out. This done, we cuter the page in which it is written, viz. 2, in the index, in the space B e, from which time all subjects under the head Be come into the second and third pages. The Index Rerum of the Rev. Dr. Todd differs from the common-place book of Locke, in being intended rather as an index to subjects that occur in the course of one's reading than a common-place book. Instead of the passage being copied out in full, the substance of it is given, and the book and page referred to. instructions that he lays down are-1. To have the index constantly at hand when you read; and when you meet with anything of interest, just note it down,the subject, the book, and the page, and any word designating its qualities. 2. Make your index according to the subjects as much as possible, selecting that word which best conveys the idea of the subject. wide margin is to contain the word selected as a guide to the subject, and noted down on the corners of the page are the letters of the alphabet (capitals), and in the centre the first five vowels, a, e, i, a, u; each letter of the alphabet having two pages to each of the vowels, and consequently each letter having ten pages. when you read anything which you may hereafter need, place the principal word in the margin under the first letter in that word and the first wowel in it. For students and literary men, this system is preferable to that of Looke. The following are a few of the examples given :-

# Common Pleas

COMMON PLEAS. (See Count.)
COMMON PRAYER. (See LITTERY.)
COMMON SERSE PRILOSOFHY is a term employed to
designate a certain system of philosophy which professes to accept the testimony of our faculties as trustworthy within their respective spheres. The results of Bishop Berkeley's philosophical speculations led him to the conclusion that there was no such thing as a material world—nothing in nature but spirits and ideas; material world—nothing in nature but spirits and ideas; and that the belief in material substances and of abstract ideas is the chief cause of all our errors in philosophy, and of all infidelity and heresy in religion. Hume proceeded upon the same principles, but carried them to their full length, and as the bishop undid the whole material world, Hume, upon the same grounds, undid the world of spirits, and left nothing in nature libit ideas and impressions, without any subject on which but ideas and impressions, without any subject on which they might be impressed. Then appeared Dr. Thomas Reid with his philosophy of common sense. "I observe," he says, "that as the Peripatetic system has a serve," he says, "that as the reripatent system has a tendency to materialize the mind and its operations, so the Cartesian has a tendency to spiritualize body and its qualities. One error, common to both systems, leads to the first of these extremes in the way of analogy, and to the last in the way of reflection. The error I and to the last in the way of reflection. The error I mean is that we can know nothing about body or its qualities but as far as we have sensations which resemble those qualities. Both systems agreed in this; but, according to their different methods of reasoning, they drew very different conclusions from it; the Peripatetic drawing his notions of sensation from the qualities of body, the Cartesian, on the contrary, drawing his notions of the qualities of body from his sensations. The way to avoid both these extremes is to admit the existence of what we see and feel as a first principle, as existence of what we see and feel as a first principle, as well as the existence of things whereof we are conscious; and to take our notions of the qualities of body from the testimony of our senses with the Peripatetics, and our notions of our sensations from the testimony of consciousness with the Cartesians." The philosophy of common sense has been ably vindicated by the late Sir William Hamilton, in one of his notes appended to his edition of Reid's works. He maintains that his edition of Reid's works. He maintains that the end of all philosophy is truth, and consciousness is the instrument and criterion of its acquisition; that philosophy is thus wholly dependent upon consciousness; that consciousness is to be presumed trustworthy until proved mendacious; that no attempt to show that the data of consciousness are (either in themselves or their necessary consequences) mutually contradictory has yet succeeded; and the presumption in favour of the truth of consciousness, and the possibility of philosophy, has therefore never been redargued. "Nature is not gratuitously to be assumed to work not only is not gratuitously to be assumed to work not only in vain, but in contradiction of herself; our faculty of knowledge is not without ground to be supposed an instrument of illusion; man, unless the melancholy fact be proved, is not to be held organized for the attainment, and actuated by the love of truth, only to become the dupe and victim of a perfidious creator."

become the dupe and victim of a perfidious creator."

—Sir W. Hamilton.
COMMON TIME, in Mus. (See TIME.)
COMMONS, HOUSE OF. (See PARLIAMENT.)

—NOMMONWEALTH OF ENGLAND, kom'-mon-welth, was that form of government established in England on the death of Charles I. in 1649, and which existed during the protectorate of Oliver Cromwell and his new Richam with the abdication of the Inter and the restoration. Immonarchy again in the person of Charles II. 11459.

COMMUNIX, kom'-mune, in France, is a subordinate

COMMUNE, komi-mune, in France, is a subordinate territorial subdivision of the country, less than a canton, and corresponding in some measure to an English parish. A commune includes sometimes a single town,

# Company

hence a person is said to be in communiou with a church who declares his acquiescence in its doctrines and participates in its worship. Different churches, too, are said to be in communion when they are maked in doctrine and discipline. Communion is applied in m nourme and discipline. Communion is applied; in a more limited sense, to participation in the secrement of the Eucharist or Lord's Supper. (See Euchalize Communion denotes that all who have been baptized, either in infancy or adult age, may, on a credible profession of their faith, sit down at the Lord's table with others of different denominations. Strict communion, on the contrary is confined as Strict communion, on the contrary, is confined to a particular denomination. Communion service is the office in the Liturgy of the Church of England for the administration of the Eucharist. Communion clements are the bread and wine employed in the Eucharist.

COMMUNISM. (See SOCIALISM.)
COMMUNISM. (See SITHES.)
COMMUNISM. kom-pan'-yan (Fr. compagnon), a kind of wooden porch placed over the entrance to the master's cabin in merchant-vessels.

COMPANION-LADDER, a ladder used in men-of-war, by means of which the officers ascend to or descend

from the quarter-deck.

COMPANY, kum'-pane (Fr. compagnie), an association of merchants, mechanics, or other traders, joined together for one common interest. In all municipal corporations the mechanics are united into companies, with privileges and large immunities bestowed on them by royal charter. Their original object was the pro-tection and advancement of trade. Their powers have been considerably restricted in late years. The term company is more particularly appropriated to those large associations set on foot for the purpose of carrying on some industrious or commercial undertaking. ing on some industrious or commercial undertaking. Companies, in this seuse, are generally divided into two great classes,—regulated companies and joint-stock companies. In open or regulated companies, the affairs are managed by directors appointed by the members; but there is no joint stock. Any person properly qualified can be admitted as a member if he pays a fine and agrees to submit to the regulations of the company, and each member trades upon his own stock and at his own risk. The regulated companies formerly existing in this country resembled the corponormerly existing in this country resembled the corporations of trades, and were a sort of enlarged monopolies. They now exist only in name, and do not maintain a monopoly in any branch of trade. Exclusive, or joint-stock companies, differ not only from regulated companies, but from private copartnerabips. An institution of this sert is a company, having a certain amount of capital divided into a small or great number of transferable shares, manged, for the common advantage of the shareholders, he a hody of directors advantage of the shareholders, by a body of directors chosen by and responsible to them. The South-Sea Company and the East-India Company are two of the largest institutions of this kind which have been organized in Great Britain. The former arose out of the inability of the government to pay the sailors of the royal navy during the long war with France in the royal navy during the long war with france in the reign of Queen Anne. The tickets with which the sailors were paid fell into the hands of usurers, and the nation found itself indebted £9,471,321, and no means provided for paying it by parliament. The chancellor of the Exchequer, Harley, afterwards earl of Oxford, proposed a scheme by which he allowed the proprietors proposed a scene by which he showed the proposedra of these debts 6 per cent. per snuum, and incorporated them for the purpose of carrying on a trade to the South Sen. The fatal South-Ses bubble scheme was projected in 1720, and was executed upon the statute 6 George I., wherein it was declared that the company wight redeem all or now of the redeemable neticual might redeem all or any of the redeemable national debts. Its pretence was that of raising a fund for carrying on a trade to the South Sea, and purchasing carrying on a trade to the South Sea, and purchasing and sometimes several villages, and each has a mayor annotation and a communal municipality. There are upwards of 37,980 communes in France.

Communicating, kom-mu'-ne-kai-ting, in Theol., is the act of receiving the sacrament of the Eucharist. (See Eugarist.)

Communion, kom-mu'-ne-on (Lat. communto, mutual participation), in a general sense, denotes fellowship or intercourse between two or more persons. In sold for £300. In three months' time it fell to £150, Theol. it is fellowship with an particular church; and sold for £300. In three months' time it fell to £150, Theol. it is fellowship with an particular church; and

ful scenes of wretchedness and distress resulted, and all the directors were severely fined, and many lost their untire property. This did not, however, interfere with the Seuth-Sea Company, which, in the year 1722, had a capital of £33,800,000. In 1748 the whole of their trading stock was converted into an annuity stock, and the company ceased in every respect to be a trading community. The East-India Company was formed under a charter granted for fifteen years by Queen Elizabeth, in 1600, under the title of "The Governor and Company of Merchants of London trading to the East Indies." The charter was exclusive, prohibiting the rest of the community from trading within the the directors were severely fined, and many lost their East Indies." The charter was exclusive, prohibiting the rest of the community from tracing within the limits of the company, which comprised the whole space, including both land and sea, between Cape Hora and the Cape of Good Hope. Ships were soon sent out by the company to Sumatra and Java, which returned with cargoes of calico, silk, indigo, &c.; and about 1612 they obtained leave from the native rulers to establish factories at Surat, Ahmedabad, Cambay, and Care. The two of Surat was considered the The town of Surat was considered the principal British station in the west of India, till the was frequently renewed, and their stations and fac-tories increased in number. The station and fac-tories increased in number. The station at Madras was established in 1640, that of Calcutta in 1645, and that of Bombay in 1665. By a statute of Charles II. they were empowered to make war and peace on the native princes, and for nearly two hundred years they native princes, and for nearly two hundred years they took advantage of this privilege. A new East-India Company was formed in 1698, to whom the crown granted a charter, because they offered a loan of 22,000,000 to the state. The two companies could not agree, so they amalgamated, and formed one company, under an act of parliament passed in 1702. As long as the company existed, the constitution, as then formed, remained almost the same. Every shareholder who held £500 of the company's stock became a member of the Court of Proprietors. This court chose from their number twenty-four directors, each of whom held not less than £2,000 of the stock. The Board of Control, which was afterwards formed, had reference to the affairs of Indian government. The members of the East-India Company were, properly speaking, merchants exporting home produce and importing silk, calico, diamonds, spices, &c., from thence. Gradually, they began to interfere in the quarrels of native princes, and, in time, began to gain an influence which amounted to sovereign power over vast portions of territory. From this period they over vast portions of territory. From this period they could not obtain a renewal of their charter without a loan to government, and in 1835 their trading privi-leges were taken away. Their dividends had to be paid by means of taxes levied on the people of India. The wars that have occurred since that time have been waged by this country as a nation, and not by the company. The last charter would have remained in company. The last charter would have remained in force until 1873, had it not been for the Sepoy rebelion in 1857. Notwithstanding a vigorous resistance, the company were then compelled to give up their powers, and it was resolved that the management of India should be concentrated in the hands of the British government. In 1858, the whole of the company's powers were transferred to the crown. The East-India Company is still in existence, but solely for the purpose of receiving and paying dividends. The Hudson's Bay Company is another institution of the same kind, but smaller. They received their charter in 1670, for the exclusive right to trade in the vast territories which surround Hudson's Bay. They erected several forts on the western side of the bay, which were taken and destroyed by the French in bay, which were taken and destroyed by the French in 1782. For a considerable period, this company carried on a lucrative trade in the skins and furs of animals, which were found in great abundance in these districts, and were of much finer quality than those found it less and were of much nner quality than those found these bortherly countries. On the formation of the North-West Company, they met with serious rivals; and when Lord Selkirk became a partner in the Hudson's Bay Company, many scenes of violent and sanguiarry contest took place between the servants of the two parties. In 1821 these disputes were settled by a conlition of the two companies, and the extensive fur trade was carried on with their united capital. At the

to large institutions, such as the Bank of England, railway companies, &c., where the operations are quaducted by means of agents acting under the orders of a board of directors.

COMPANY, in Mil., is the ordinary term given to a body of men in the guards, the line, or the marines, under the command of a captain. In the cavalry a captain's command is called a troop; in the artillery, a battery. The strength of a troop of cavalry and of a company in the line is eighty men of all ranks; of a battery of artillery, 120. In the volunteers, the minimum strength of a company is sixty men of all ranks, and the maximum, 100. A company is divided into subdivisions, and each subdivision into two sections. subdivisions, and each subdivision into two sections.

A sergeant and corporal are allowed to each section, and a fifth sergeant acts as captain's covering sergeant.
The first mention made in history of the division of
an English regiment into companies under a captain, lieutenant, and ensign, is at the battle of St. Quentin in 1557, when the French were defeated by the allied Spanish and English forces. The crew of a vessel is

often called the ship's company. COMPARISON, kom-par-e-sun (Fr. comparaison), in Phil., is the act of carrying the mind from one object to another, in order to discover some relationship subsisting between them. The result of comparison

is a judgment.

COMPARISON, in Rhet., is a figure of speech frequently employed for the ornament of composition; and, when properly introduced, it adds much to the beauty of style. It consists in viewing two things with beauty of style. regard to a third, which is common to them both. Comparisons are of various kinds; but they may be all arranged into one or other of two clauses, according us they are addressed to the understanding, with a view to instruct, or to the heart, with a view to please. The latter of these purposes is accomplished in various latter of these purposes is accomposited in various ways:—(1) By suggesting some unusual reasonblance or contrast; (2) by setting an object in the strongest light; (3) by associating an object with others that are agreeable; (4) by elevating an object; and (5) by depressing it. The great pleasure in the art of agraparison lies in discovering likenesses between things of the contraction and where was result and at at 15 feet. different species, and where we would not, at first glance, expect a resemblance. Hence the objects compared should not bear too near and obvious a re-semblance to each other. Neither ought comparisons to be founded on likenesses that are too faint orremote.

to be founded on likenesses that are too faint or remote, nor to be carried beyond certain bounds.

Comparison, in Gram, is the means by which is denoted the degree in which the quality expressed by an adjective is possessed by the substantive with which it is coupled. There are three degrees of comparison,—the positive, comparative, and superlative. The positive expresses the quality simply, without any comparison; as good, wise, prudent; and, hence, some do not consider this as a degree of comparison. The comparative expresses that the quality is possessed in a higher degree by that object than another; as, John is taller than James. The superlative expresses the possession of the quality in the highest degree, or in a higher degree than it is possessed by a number of in a higher degree than it is possessed by a number of others; as, Solomon was the wisest man; James is the best scholar in his class. In English, there are two ways of expressing these degrees; either by an inflection or change on the word itself, as wise, wiser, wisest; or by the addition of a word, as prudent, more prudent, most prudent. In many cases, either form may be adopted; but where the former would produce a harsh word, or one difficult to be pronounced, the latter mode is adopted. Adverbs are compared in the same way as adjectives.

COMPASS, kum'-pas (Fr. compas) .- This instrument, generally known as the mariner's compass, consists, in its simplest form, of a small box, in the bottom of which is placed a card with a diagram printed on it, similar to that in the accompanying illustration. Ex-actly in the centre of the card a fine steel pin is inacty in the centre of the card a nue steel pin a inserted, and upon this a light bar of steel, called the needle, is balanced. This needle, when magnetized and suspended on the point of the pin, has the property of turning its ends towards the north and south, varying slightly from a line drawn due north and south by a declination either towards the east or west, which present time, the name of company is expressly given differs in extent at different times, and to such a degree

### Compass

that it is not uniform even for the space of twenty-four hours at any place on the earth spurface. (3ce DECLEARING). In the diagram on the card, the circle represents the horizon, and the person using the compass must imagine himself to be standing within it. The entire circumference is divided into thirty-two squal portions by lines diverging from the centre, called points or rhumbs. The points marked N. S. E. W. are called the cardinal points. (See CARDINAL PRINTED.) The north point is distinguished by a fauras-lie. It will be readily seen, on an inspection of the diagram, how the notation of the points between any two of the cardinal points is managed; thus the point makesy between N. and W. is called N.W., or north-west,—a combination of the letters of the cardinal points between which it lies being used to denote it; that between N.W., and N. is called N.N.W., or north-west,—a case; and that between N. and N.N.W., N.-W.,

MARINER'S COMPASS.

or B. b. W. as it is usually written; meaning north by It may be remarked that whonever a hyphen or connecting mark is used between any two letters in the diagram, the word "by" must be expressed when congram, the word oy must be expressed when reading the points of the compass; and it will be seen that the points which lie on either side of the cardinal that the points which he on either side of the cardinal points, and the points that are midway between these, must be read in this way. The angular distance between any two points is 11° 16°, as the horizon is divided into 360°, and each space between the rhumbs is consequently represented by 360° divided by 32. Different shapes have been adopted for the needle at various shapes have been adopted for the needle at various that it is some to be now submovindered that it. ; but it seems to be now acknowledged that it abould be as light as possible, and in the shape of a very thin prism, placed in such a manner that its narrow sides are turned upwards and downwards, one towards the eye of the spectator and the other towards the card. It was formerly the custom to make a hole in the centre of the flat bar that was used as the needle for the reception of an agate cap, to work on the point of the pin on which the needle is balanced; but it is now considered better that the needle should have no perferation through its centre, but that a hole of little depth should be drilled into the lower side of the prism, that it may be suspended on the pin at a point a little below its centre of gravity, which causes it to possess greater sensibility, with as much freedom of action as before. When the compass is placed on board ship, it is suspended by gimbals (see Gimbals), so that it may always be horizontal, whatever may be the position of It is inclosed in a box called the binnacle the ship. It is inclosed in a box called the binnacic (see BINNACLE). The great requisites in a good compass are, that the motion of its needle should be steady, as well as active and sensible, without oscillation, and that it should be so contrived that it may be easily corrected when deviation is caused by any local attraction. Many attempts have been made to correct distributions as and in the construction of reasels, chiefly from the iron used in the construction of vessels, by surrounding the compass with bars of soft iron or magnets, that will attract the needle in a contrary direction to that in which it is drawn by the metal on heard, and so counteract and neutralize its effects. The methods suggested by Professor Airey, the Astronomer Royal, scribin and Mr. Gray of Liverpool, are considered the best; maps. 512

# Compasses

but the correction of local attraction seems, under any circumstances, to be attended with considerable difficulty and uncertainty. In the royal navy, when compasses have been placed on board a vessel, they are corrected, for the influence of local attraction, by what is termed "swinging" the ship. The ship's head is brought round to every point of the compass successively, and the differences in the bearings, indicated by the compass on board and an azimuth compass on shore, under the charge of an intelligent officer, are carefully noted and registered. The results thus obtained form what is called a correcting card for the vessel in question. The Chinese assert that the mariner's compass was invented by the emperor Houangti, about 2834 n.c., and that it was then used to enable them to direct their course to any distant point on land. The sailors who navigated the Indian Ocean and Eastern seas were well acquainted with its use in the 3rd century after the Christian era, when it was quits unknown in Europe, where it is said to have been introduced by Marco Polo on his return from his travels in the East, about 1260. Flavio Gioja, a Neapolitan sailor, effected considerable improvements in it, and brought it into the form in which we now have it about 1300. Columbus is said to have discovered the variation of the compass in 1492; but this is considered to be doubtful. The inclination or dip of the needle (zee Needle, Dipping, in 1576.

COMPASS, in Mus., a term used to express the extent of notes or sounds comprehended by any voice or instrument.

COMPASS, AZIMUTH.—This instrument is a compass used at sea to find the magnetic azimuth (see AZIMUTH) of the sun or any other heavenly body. It resembles the ordinary mariner's compass in form and general principles; but the circumference of the exterior circle of the diagram on the card is divided into degrees, and a ring is fitted to the top of the box, on which two sights are fixed in a vertical position, exactly opposite to each other, with a longitudinal slit in each, through which an observation of any object can be taken. The needle shows the bearing of the object towards which the sights are directed, with regard to the magnetic pole, and the angular distance thus obtained is its azimuth.

Compass of Voices in Choreses.—Voices are of different kinds; viz. the soprano, or trible, the contralto, the trnor, and the beas. The first of these is in extence, equal with the tenor, but is in pitch an octave higher. The soprano parts are often written in the C clef, on the bottom line of the staff. The extent of the contralto is about the same as the bass, but an octave higher; that of the tenor the same as the soprano, but an octave lower; and that of the bass the same as the contralto, also an octave lower. Voices, if compelled to sing above their medium note, so no become fatigued, and fluish by screaming; again, if required to sing below the medium of the voice, they are deficient in power, and render the harmony feeble and indistinct.

Compasses, kum-pit-ses, mathematical instruments principally used for drawing circles, arcs of circles, ellipses, &c., and for measuring and transferring distances. There are many kinds of these instruments, known as common compasses or dividers, hair compasses, triangular compasses, proportional compasses, beam compasses, and calliper compasses (Née Caterre, Care Caterre, Care Caterre, Caterre,

COMPETERION, home po-tish un (Lat. competitio, from competo, I strive after something in company or together), is the act of seeking or endeavouring to gain genery, is the act of seeking or endeavouring to gain what snother is seeking or endeavouring to gain at the same time. In Pol. Boon, it is that struggle after wealth that is constantly going on in the world, and that leads the purchaser to seek the best article he can at the leads the purchaser to seek the best article he can at the lowest price, and the producer to furnish the best article at the lowest price. Socialists, and others ignorant of the principles of political economy, have declaimed vehemently against competition, and charged npon it all the economical evils that at present exist. There are, doubtless, evils connected with competition; but it is not the less certain that it prevents evils that are much greater. "Instead of looking," says J. S. Mill, "upon competition as the baneful and anti-social mail, "upon competition as the baneful and anti-social principle which it is held to be by the generality of socialists, I conceive that, even in the present state of society and industry, every restriction of it is an evil, and every extension of it, even if for the time injuriously affecting some class of labourers, is always an ultimate good. To be predeted exists computer to the control of juriously arreading some class of natural states are ultimate good. To be protected against competition, is to be protected in idleness, in mental dulness; to be saved the necessity of being as active and as intelligent as other people."—"It is the common error of socialists to overlook the natural indolence of mankind,—their tendency to be passive, to be the slaves of habit, to persist indefinitely in a course once chosen. Let them once attain any state of existence which they consider tolerable, and the danger to be apprehended is that they will thenceforth stagnate,—will not exert themselves to improve, and, by letting their faculties rest, will lose even the energy required to preserve them from deterioration."—(Principles of Political Economy.) Wherever competition is not, monopoly exists, and monopoly in all life forms is the traction. Economy.) Wherever competition is not, monopoly exists, and monopoly, in all its forms, is the taxation of the industrious for the support of indolence; if not of the industrious for the support of indolence; if not frapacity. With the exception of competition among labourers, all other competition is for the benefit of the labourers, by cheapening the articles they consume; and even in the labour-market, it is a source, not of low, but of high wages, wherever the competition for labour exceeds the competition of labour exceeds the competition of labour the never could be a cause of low wages, save by the overstocking of the labour-market. On the establishment of the Branch coverigned concernment of 1848. ment of the French provisional government of 1848 an attempt was made to do away with the natural system of competition among workmen, and to re-munerate a number of workmen alike. A special experiment was tried at the Hôtel Clichy with a govern-ment order for the uniforms of the National Guard, Fifteen hundred tailors were assembled, and were allowed two frances a day as subsistence-money while they worked, and the balance between the sum paid and what the work would have cost had it been executed by an army contractor, was to have been equally di-vided among them afterwards. It was found, how-ever, when the day of reckening came, that not only there no balance to be paid, but that there was an actual loss, and that the two frances a day of subsistence-money, the lowest rate of wages paid to tailors under the competitive system, had overpaid them for the work actually done. Their energies, unexcited by the spirit of competition, relaxed when each man found that the proceeds of his increased exertions were not to be received by himself alone, but to be disretained to be received by binusell alone, but to be dis-tributed over the whole body of his fellow-workmen; and even the thought of "liberty, equality, and fra-ternity," was insufficient to incite them. (See So-CIALISM.)

COMPLEXION, com-plek'-shun (Lat. complecto, I comprise), a term employed to signify the colour of the face and skin, although properly it means the temperament, and natural disposition of the body. Formerly, the human skin was supposed to consist of only two parts,—the cuticle, or epidermis, and the cutis, omy two pares, the cuttlets or challengths, and the cuttle, or real skin; but Malpighi showed that between these two was a soft gelatinous cellular texture, which he distinguished by the title rets mucosum. On this discovery that anatomist offered a suggestion as to the colour very that anatomist outer a suggestion as to the colour of negroes. The rete success is of very different colour in different nations; and the difference of its colour corresponds so exactly with the difference of their complexions, that there can be little doubt that it is the principal seat of the colour of the human com-

plexion. Of the different colours observed amongst mankind, Dr. Hunter gives the following view:—Black,—Africans under the line, and the inhabitants of New Guinea and New Holland. Swarthy,—the Moors in the northern parts of Africa, and the Hottentots in the southern parts. Copper-coloured,—the East-Indians. Red-coloured,—the American Indians. Brown-coloured,—the Tartars, Persians, Arabs, Africans on the Mediteranean coast, and Chinese. Brownish,—the inhabitants of Southern Europe, Sicilians, Spaniarde, and also the Abyssinians in Airica. The Turks, Samoides, and Laplanders, are also brownish. White,—most of the European nations, including the Swedes, Danes, English, Germans, Poles, &c., together with the inhabitants of the islands in the Pacific Ocean.

COMPLUTENSIAN POLYGIOT, kon-plu-tensk-gon, is

COMPLUTERSIAN POLYGLOT, kom-plutensk-gan, is the name given to an edition of the Holy Scriptures published in 1522 at Alcals de Heunres (the ancient Complutum) at the expense of Cardinal Ximenes. The first four volumes comprise the Old Testament, in Hebrew, Latin, and Greek, in three distinct columns, the Chaldee paraphrase being at the bottom of the page, with a Latin interpretation; the fifth volume page, with a Latin interpretation; the latin volume contains the New Testament in Greek, with the Latin Vulgate and interpretations of the Hebrew, Chaldee, and Greek names. The sixth volume is filled with various critical tracts. Only six hundred copies of this edition were thrown off, and the work is scarce and

expensive.

COMPOS OF NON COMPOS, MENTIS. (See INNANITY.)

COMPOSER, kom-po'-zer, literally, a practical musical author, or, in other words, one who invents or composes new music according to the established rules of science, and who studies harmony and melody as connected with effect in composition, independently of the laws of acoustics, or the philosophy of sound. As poser must not be confounded with a theoretical mu A.oom. author, whose business it is to speculate in acoustics, and write on the laws of harmony and melody, but not to interfere with their practical application in composition.

COMPOSITE, kom-poz'-e-fe (Lat. compone, composition, I put together), in Bot., a nat. ord. of dicotyledonous plants, in the sub-class Corolliform. It is one of the largest and most important orders in the vegetable kingdom, and its members are to be met with in all parts of the world. In northern regions the plants are generally herbaceous, but in warm climates they sometimes become shrubby, or even arborescent. The following botanical characters clearly define this great following botanical characters clearly denne the great order:—The leaves are alternate, or opposite, and without stipules; usually simple, but often much divided. The flowers, which are termed flores, are hermaphrodite, or unisexual, are collected in dense heads or eapitula, each collection of florest being on a common receptacle, and surrounded by an international collection of florests. involucre. The separate florets are also frequently furnished with scale-like bractlets, termed pales of the number with scale-like oracticis, termed patter of the everytable. The callyx is superior, closely adhering to the ovary, its limb being entirely abortive, or membranous, or pappose. The corolla is monopetalous, tubular, superior, and usually deciduous; it is ligulate (strap-shaped), bilabiate (two-lipped), or fannel-shaped; in the latter case, four or five-toothed. The shaped; in the latter case, four or five-toothed. The stamens are five in number, rarely four, and are inserted upon the corolla; the filaments are either distinct or monadelphous, and the anthers are united into a tube. The ovary is interior and one-celled, with a single crect ovule. The etyle is simple, undivided below and bifid above; the stigmas are placed upon the inner surfaces of the two divisions. The fruit, termed a cypsela, is dry, indehiscent, one-celled, and crowned with the limb of the calyx, which is often pappose. The seed is solitary, erect, and exabuminous. The order has been subdivided by De Candolle into the following sub-orders:—1. Twalkilara.—Porets tubular. or order has been subdivided by De Candolle into the following sub-orders:—1. Thoughtfora,—florets tubular or ligulate, either perfect, unisexual, or neuter; when perfect they are tubular, with five, or rarely four, equal teeth. 2. Labiatifora,—hermaphrodite florets, or at least the unisexual ones divided into two line. or at reast the uniserial ones divided into which Liquifform.—florets all ligulate and perfect. The first of these sub-orders includes the sections Corymbifers and Cysarocephola, proposed by Jussieu: the last corresponds to the Chicoracea of the same writer. Plants belonging to the sub-order Tublifform abound.

# Composite Candles

principally in hot climates. They are remarkable for their bitter, tonic, and aromatic properties. (See ANTHEMIS, ARTEMISIA, ARMICA.) A few are used for ATTEMES, ARTEMISIA, ARMSOA.) A few are used for dysing. (See Carthauts.) Some are cultivated as esculent vegetables, as the artichols and cardoon. (See these words.) The Labiatiflora are almost confined to the extra-tropical parts of South America. They do not furnish many affectul products. The Liquififora are most abundant in cold and temperate climates. Their chief characteristic is the presence of a milky, hitter matterior or narrotic nine, which possesses bitter, astringent, or narcotic juice, which possesses ulterative, diuretic, aperient, or narcotic properties. The roots of some are esculent, and others, by cultivation with diminished light, become edible as salads. (See Cichorium, Lactuca, Taraxacum.)
Composite Candles, kom'-pos-ite, a name applied

COMPOSITE CANDLES, kom'-pos-ife, a name applied to candles made of different mixtures of ordinary tallow and stearine. They are less hard according to the amount of tallow they contain.

"COMPOSITE NUMBER, in Arith., is one which can be divided by some other number greater than 1, in opposition to a prime number, which cannot be thus divided. Thus 12, 15, and 27 are composite numbers; whilst 11, 47, 59 are not composite. 47, 89, are not composite.

COMPOSITE ORDER. (See ABCHITECTURE.)

COMPOSITION, kom-po-zish'-zum (Lat. compositio), in a general sense, is the act of forming a whole or integral of various dissimilar parts, and is also applied to the body or compound thus formed. In Lit. it is the art of forming and combining deas, and clothing them with language suitable to the nature of the sub-ject. In Log. it is a method of reasoning in which we proceed by gathering together a number of ideas, and combine them into one system, otherwise called syn-thesis. In Gram, it is the joining of two words to-gether, or prefixing a particle to a word, to augment, diminish, or change its signification.

COMPOSITION denotes the art of producing new music according to the established rules of harmony and modulation, and of arranging musical sounds into airs and songs, &c., either for the voice or instruments. airs and songs, &c., either for the roice or instruments. Composition includes melody, or the art of making a single part, and harmony, or that of disposing and concerting several single parts together, so that they may form one agreeable whole. As the musical scale consists only of twelve sounds, a careless observer might imagine that all the possible combinations of those twelve sounds would in time be exhausted, and thus bring composition to an end. It is not so, however, for these targles counds will admit by were combined. for these twelve sounds will admit, by mere combins tion, of 144 different successions, and each of these combinations may be again varied by length, rapidity, force, leguto, and staccato, so as to admit of the construction of many million of tones ; thus, no end can be found to composition, or any excuse made for wearisome monotony.

COMPOSITOR. (See PRINTING.)

COMPOSITOR. (See PRINTING.)
COMPOSIT. (See MANURES.)
COMPOUND INDEREST. (See INTREST.)
COMPOUND RADICLES, kom'-pownd (Lat. compono),
Chem., certain combinations of elements which behave towards acids and bases in the same manner as the elementary bodies. Cyanogen, for instance, which is a compound of carbon and nitrogen, forms compounds with the metals in the same manner as oxygen or chlorine; and ethyl, which is a compound of carbon and hydrogen, acts towards the acids in a similar. manner to iron or lead, forming salts in a precisely parallel way. (See ORGANIC RADICLES.)

Coirpensus way. (see Ones in the light of the compre-density), in Phil, is that act of the mind whereby it apprehends or knows any object presented to it on all the sides on which it is capable of being apprehended

or known.

COMPRENENSION, in English Church Hist., is the name of a scheme proposed on several occusions for relaxing the terms of conformity, and admitting dissenters into community with the Church. It was proposed by Bridgman and Sir Matthew Hale, but without success; and subsequently Tillotson and Stillingfleet attempted it; but the bishops refused their assent. The scheme was revived again after the Revo-Intion, but without success, and at length the Act of Teleration was passed. (See TOLERATION.)
COMPTROLLER, (See CONTROLLER.)

# Conchold

Oon, kon, is a Latin inseparable preposition, which, at the beginning of words, signifies union; as concernse, a running together. In Mus., it signifies with; as, con affetto, with tenderness.

CONCATENATION, kon-kdf-s-naf-shun (Let.), in Phili-denotes the connection that exists between a number of things linked together or dependent on each other.

CONCAVE, kon'-kato (Lat. concavus). — A curve or surface is said to be concave on the side on which straight lines drawn from point to point in it fall straigue mes grawn from point to point in it fail between the curve or surface and the spectator; that side is convex on which the curve or surface falls be-tween the lines and the spectator. Thus the inner surface of a hollow sphere is concave, while the outer (See LRNS.) surface is convex.

CONCAVO-CONCAVE, OF DOUBLE CONCAVE.-Terms applied to lenses which are concare on both sides; when one side is plane and the other concave, the lens

is said to be plano-concave.

Concavo-Convex, or Meniscus, a lens having one side concave and the other convex. When one side is plane and the other convex, the lens is said to be planoconvex; and if both sides are convex, it is a double convex.

CONCEALMENT OF BIRTH. (See INFANTICIDE.) CONCEPTION, kon-sep'-shun (Lat. conceptio), in Phil., is the simple apprehension or perception that we have of any object, without proceeding to affirm or deny anything regarding it.

CONCEPTION, IMMACULATE. (See IMMACULATE

CONCEPTION.)

CONCEPTION OF OUR LADY, NUNS OF THE ORDER OF, a religious order of nuns, founded by Bestrix de Sylva, sister of James, first count of Portalegro, in Portagal. Pope Innocent VIII. confirmed the order in 1439, and granted them permission to follow the rule of the Cistercians. After the death of Beatrix, they were placed under the direction of the Franciscans, as the most zealous defenders of the immaculate conception, and, at the same time, they were required to follow the rule of St. Clara. Their dress consists of a white gown, blue mantle, and scapulary, on which is an image of the Virgin.

CONCERT, kon'-sert (Ital. concertare), a musical entertainment, in which a number of rausicians, both vocal and instrumental, unite in the exercise of their various talents. Concerts sometimes consist of vocal music only. These are distinguished by the name

of vocal concerts.

CONCERTINA, kon-ser-tel-na, a kind of musical wind instrument, patented by Professor Wheatstone in 1829, which is said to bear a greater resemblance to the human voice than any other yet invented. A bad opinion has been formed of this instrument by many people in consequence of their having mistaken for it the so-called German concertina, which is indeed only an improved accordion, shaped like a concertina. real, or, as it is called, the English concertins, is both constructed and fingered in a totally different manner, and although the sounds are produced on the same principle as those of the accordion, there is no more similarity between them in performance than there is between a common whistle and a German flute. instrument has a compass of three octaves and a half, and possesses not only a chromatic, but an enharmonic scale, it having two separate tones. From this fact, as well as from the flexibility of the bellows, the chords are better in tune than in most other instruments of a fixed sound. Its capabilities are such that the most complex harmonies, as well as the most difficult violin complex narmonics, as were as the most dimental violin or flute music, can be played upon it. It also possesses the great advantage of being learnt in a very short time. The best instruction-books for this instrument are, perhaps, those by Giulio Regondi, Professor Wheatstone, and C. Coule.

CONCHIFERA, kon-kif'-e-ra (Lat. concha, a shell: fcro, I bear), the scientific name given to cortain bavalve shells, whose inhabitants are susceptible of no other impressions save those of immediate confact.
The three orders into which this family is divided are

the Brachiopoda, Dimyaria, and Mohamyaria.

Concholo, kon'-koid Gr. konchos, a shell), the name of a curve invented by Nicomedes. It was much used by the ancients in the construction of solid pro-blems. It had for its objects the trisection of an angle,

# Conchoidal

the construction of two geometrical means between two given lines, and the doubling of the cube. Me chanically the curve may be easily described, and is often used in architecture as a boundary-line of the vertical section of columns.

CONCENTIAL ken-key'dil (Lat. concha, shell; Gr. cidos, form), in Min., a term applied to that peculiar fracture of stones and minerals which exhibits convex and conceve surfaces. Flint, cannel coal, and glass, are examples of substances possessing a conchoidal fracture. fracture.

CONCHOLOGY. (See MOLLUSCA.)
CONCHOLOGY. (See MOLLUSCA.)
CONCLAVE, kon'-klaiv (Lat., a private room), is the
name given to the assembly of cardinals, met together
for the purpose of electing a pope, and it is also applied
to the place in which they meet for that purpose. The concleve is usually laid in the Vatican, where on the day after the funeral of the deceased pontiff, they all assemble, and, after the regulations that relate to the conclave have been read, they are locked up in separate apartments, and kept under strict surveillance until the alection has taken place. separate spartments, and kept under strict shrenshine until the election has taken place. They meet once a day in the chapel of the palace, when a scrutiny is made of their votes, and this is repeated every day until at least two-thirds of the votes are in favour of one individual, who is then considered as duly elected to the pontifical chair. Conclusist is a spiritual or secular attendant on a cardinal during a concluse. Each cardinal has one such attendant, who has to take a vow of inviolable silence, and is not allowed to leave till the business is over, except on the ground of dangerous illness.

CONCLUSION, kon-klu'-zhun (Lat. conclusio), in Log. is that proposition which is inferred from certain preceding propositions, called the premises of an argument.

CONCORD, kon'-kord (Lat. concordia, Fr. concorde), in Mus., is the union of one or more musical sounds, which, by harmonizing and agreeing together, produce an agreeable effect upon the ear. When any two single sounds bear so much relation to one another that, on being sounded together, they make a compound sound, that relation is called concord. Concords are of two kinds, perfect and imperfect. Perfect concords consist of the fifth and eighth, and imperfect concords of the third and sixth. These last have another distinction,-that of the reater and lesser third and sixth. Concords are again divided into consonant and dissonant. The consonant concords are the perfect concords and their derivatives; every other is dissonant. This term is also often applied to voices or instruments, with respect to their tuning; as, for instance, we say, "That instrument is not in concord," or not "in tune." "Those voices do not harmonize and agree."

CONCORDANCE, kon-kor'-dons (Lat.), "is a dictionary or index of all the important words in the Bible alphabetically arranged, for the purpose of finding passages, and of comparing the various significations of words."

The importance of a work of this kind was early perceived; and the first work of the kind in any language was the concordance of Hugo de St, Caro, about the middle of the 13th century. By far the most complete and valuable concordance to the English Bible is that and valuable concerdance to the English Bible is that by Alexander Cruden, the first edition of which was published in \$\int\_{\text{tot}}\$ to, 1737, and which has since passed through numerous editions. Perhaps the best concordance to the Hobrow text is that of J. Fürst, entitled "Concordantiae Librorum Sacrorum Veteris Testamenti Hebraicæ et Chaldaicæ" (Leipsic, 1837-40). menti Hebraicæ et Chaldaicæ" (Leipsic, 1837-40). The most recent concordance to the Greek New Testa-The most recent concordance to the Greek New Testa-nient is that of C. H. Bruder, "Omnium Vocum Novi Testamenti Græci," 4to (Leipsic, 1843). The term has also come to be applied to works of a similar nature, of other books; as the "Concordance to Shak-spenre," by Mrs. Cowden Clarke (London, 1847).—For further information on this subject see Watts's Bibliotheca Britannica; Orme's Bibliotheca Biblica; Dar-ling's Cyclopædia Bibliographica; the English Cyclo-

padia, art. Concordance.

CONCORDAT, kon-kor'-did (Lat.), is the name given to a formal agreement entered into between the pope, as head of the Roman Outholic church, and the tem-

# Concubinage

taining certain immunities for the clergy; as exemption from taxation, secular jurisdiction, &c. These have formed subjects of frequent dispute between the popular and the several states of Europe, and have given occasion to concordate settling the rights of each party in any particular state. Most of the concordats have been extorted from the popes, and have been, more or less, concessions of what the Church claims as her rights to the civil power. One of the most important of the earlier concordats was that of Worms, made in 1122, between Pope Calixtus II. and the emperor Henry V. of Germany, which has since been considered as a fundamental law as regards the relations between the fundamental law as regards the relations between the Church and the State in Germany. Sometimes, however, the popes succeeded in concluding concordats to their advantage; but since the middle of the 18th century, the Church has been obliged to resign by concordats many important privileges. One of the most remarkable of the later of these was that extorted by Napoleon, in 1801, from Pope Pius VII. By it the French government obtained the right to appoint the clergy; the clergy became subject, in civil matters, to the temporal power, and all immunities were abolished. But the most remarkable concordat of modern times But the most remarkable concordat of modern times is that which was entered into between the pope and the emperor of Austria in 1855. By it the papal power was widely extended over all the Austrian dominious, and greater privileges conceded to it than had ever before been granted by any German sovereign. By it not only has the Church sole power in ecclesiastical matters, independent of the State, but all institutions for educational purposes are under its control, and it has the power of preventing the dissemination of works of a dancetors. tion of works of a dangerous character.

tion of works of a dangerous character.

CONCRETE, kon'-krete (Lat. concrescere, to grow together), an artificial conglomerate (see CONGLOMERATE), formed by mixing hydraulic lime, water, sand, and shingle, or screened ballast, together. Hydraulic lime is made from argillaceous limestone, which, when burnt, absorbs water very slowly, without swelling, and throws out much heat. (See Lime.) In making concrete, about one part of lime is used to nine parts of shingle, and, as hydraulic mortar hardens very quickly when the lime has alsorbed as when weters. quickly when the lime has absorbed as much water as is necessary for its crystallization, these materials are mixed together before the water is added. When the whole has been thoroughly mingled, it is put, while it is still soft, in the position in which it is required for the artificial foundations of houses, the piers of bridges, &c., and allowed to harden. Concrete is quite impervious to damp, and is therefore well calculated for the foundations and floorings of the basements of buildings built on a damp subsoil, the moisture of which would soon penetrate through brickwork or flagstones.

CONCRETE, in Log., is a term employed in opposition to abstract, and is applied to a notion of an object as it exists in nature, invested with all its qualities and properties. Abstract, on the other hand, is applied to a notion of a particular property or quality, or an object thought of independently and apart from the object itself. ject itself. Thus, a just man is a concrete notion, but iustice is an abstract idea.

CONCRETIONS, kon-kre'-shuns, in Med., are hard sub-CONCLETIONS, kon-kre-anima, in Med., are nard sup-stances that occasionally make their appearance in different parts of the human body. (See Calculus.) Concumnage, kon-ku'-bin-aij (Lat.), is the cohabi-tation of a man with a woman to whom he is not legally

united by marriage. In early times this was a common practice; and men of means had frequently, hesides several wives, a number of concubines, as we read of in the Old Testament. The latter did not enjoy the same rights as a wife, and could be repudiated and dismissed at any time. Both among the Greeks and Romans concubinage was allowed; but it was not legally sanctioned amongst the latter until the time of Augustus. By the Lex Julia and the Lex Papia Popprea concubinage was legally permitted to unmarried men; but not more than one concubine was allowed, Concomance.
Concom

there exists in Germany a peculiar kind of institution under the name of half-marriage, or lest-hand mar-riage, in allusion to the manner of its being contracted. riage, mailusion to the manner of its being contracted, the man giving the woman his left hand instead of his right. It is a real marriage so far as the parties are bound to each other for life; but the woman cannot bear the husband's name or title, neither can her children succeed to his property. The common law of Germany permits this kind of marriage to princes and the nobility.

Concussion, kon-kus'-shun (Lat. concutio, a shaking together), in Med., is applied to a violent commotion or shock communicated to the brain, or the whole or shock communicated to the brain, or the whole nervous system, by collision of the body with some external object. In its slightest form, as tunning sensation is merely communicated, which passes away in a few minutes; in its severest form, death rapidly ensures. In the severer cases the patient becomes immediately pale and insensible; the breathing sometimes matural, but frequently slow and feeble; the pupil rather contracted; the puise usually slow and weak. rather contracted; the pulse usually slow and weak, but sometimes natural; the extremities become cold, the secretions are suspended, and there is frequently names and vomiting. In the treatment of concussion great caution is necessary. The patient at first should be kept warm in bed till consciousness is restored, when when or other stimulants may be cautiously administered. If he seem to be sinking, stimulants should be at once had recourse to; but so long as he remains stationary, no active means should be employed. Here, as in all other serious cases, our object is not to supersede the employment of a medical man, but merely to point out the best course to be followed till such a one can be called.

CONDENSATION, kon-den-sai'-shun (Lat. con, together; densus, close), the rendering of a body more compact, denser, or of more specific gravity, by causing its par-ticles to come into closer contact. The term is usually spplied to the process of converting a vapour into a fluid by distillation or some other method.

Condenser, kon-den'-ser (Lat. condenso, I make thick), a term used to denote any apparatus used for cooling heated vapours and reducing them to a liquid form. In ordinary distillation, the wormtub is the condenser most generally adopted. It consists of a spiral table, which passes through a tub constantly filled with sold water. The vapour enters the tube at the top, and being condensed in its passage, runs out as liquid at the bottom. The condenser of a steam-engine is that the bottom. The condenser of a steam-engine is that part attached to the cylinder where the steam is condensed. The pneumatic condenser is a syringe worked on the same principle as the force-pump, by which a large quantity of air can be forced into a given space.

CONDENSING STEAM-ENGINE. (See STEAM-ENGINE.) CONDENSIA STRAM-LAGINE. (SECTION AND ADDRESS OF THE uncertain whether it shall take effect or not; also it is defined to be what is referred to an uncertain chance which may happen or not happen. There are conditions of divers kinds; viz. conditions in deed and in law, conditions precedent and subsequent, conditions in-kerent and collateral, &c. A condition in deed is that which is joined by express words in a lease or other grant; as, if a man makes a lease of lands to another, grant; as, it a man makes a lease of lands to another, reserving a rent to be paid at a certain day, with a provise or condition that, in default of payment, the keeper of renter.—Condition in law, or implied, is when a person grants another an office; as that of keeper of a park, steward, &c., for term of life. Here, although there be no condition expressed in the grant, yet the law makes one, which is, if the grantee do not putly execute all things belonging to the office, it shall be lawful for the grantor to enter and discharge him of his office.—Condition precedent is when a lease or estate is granted to one for life, upon condition, that if the lease pay to the lessor a certain sum at such a day, then he shall have the fee-simple. In this case,

dale in fee, upon condition that the grantee shall pay to him at such a day such a certain sum, or that his estate shall cease. Here the condition is subsequent and following the estate, and upon the performance thereof continues the estate by the performance of the thereof continues the estate by the performance of the condition.—Inherent conditions are such as descend to the heir, with the land granted, &c.—A collateral condition is that which is annexed to any collateral act. Conditions are likewise affirmatics, which consist of doing; negative, and consist of not doing. Some are forther said to be restrictive, for not doing a thing; and some computery; as that the lessee shall pay rent, &c. Also some are single, to do one thing only; some computing, to do divers things; and others disjunctive. ALE. ALEO SOME are single, to do one thing only; some copulative, to do divers things; and others disjunctive, where one thing of several is required to be done.

CONDITIONAL FRE. (See FRE.)

CONDITIONAL PRE. (See FRE.)

CONDITIONAL PRE. (See FRE.)

a phrase introduced by Sir William Hamilton to denote the limited region of knowledge open or accessible to the human mind. "The conditioned," he ways, "is that which is alone conceivable or cogitable; the unconditioned, that which is inconceivable or incogitable. The conditioned, or thinkable, lies between two extremes, or poles; and these extremes, or poles, are each of them unconditioned, each of them inconceivable, each of them exclusive or contradictory of the Of these two repugnant opposites, the one is that of unconditional or absolute limitation; the other, that of unconditional or infinite illimitation." infinite and the absolute, properly so called, he holds to be equally inconceivable to us. "We must believe in the infinity of God; but the infinite God cannot by us, in the present limitation of our faculties, be comprehended or conceived. A Deity understood would be no Deity at all; and it is blasphemy to say that God only is as we are able to think him to be. We know God according to the finitude of our faculties; but we believe much that we are incompetent to know."—Ref. Hamilton's Lectures and Discussions; Mansel's Bampton Lectures.

CONDOR, kon'-dor (Sarcoramphus gryphus), a large bird of the Vulture species. It is almost strictly confined to the immense chain of the Andes, as is called the vast mountain-range that runs along the whole west coast of South America. Humboldt, who, with his companion Bonpland, passed a considerable period in these regions, and lost no opportunity of observing the condor and making the strictest inquiries concerning its habits, was cuabled to clear away much of the mystery that had hitherto attached to the bird. Premystery that had hitherto attached to the bird. Previously it was regarded as a bird of such monstrous proportions, that in its flight it cast a shadow on the earth like a big cloud, and as so feroclous as to snatch up and bear off infants, kids, and lambs in an instant. Humboldt, however, found the listle children of the Indians sleeping in the open air, while their parents were away gathering snow to sell in the neighbouring towns; and at least half a dozen condors were in sight, hovering sloit and perched on the neighbouring heights. To all his inquiries on the subject, he was answered that a single case of child-stealing by bouring heights. To all his inquiries on the subject, he was answered that a single case of child-stealing by these big birds was unknown. Yet that this arises from no lack of courage on the part of the condor is certain, for, as Humboldt was informed, two of them will even attack a heifer, pursuing it for miles, and wounding it with their beaks and talons. Gradually the poor animal will relax its speed, and from sheer exhaustion and thirst loll its tongue. Now is the condor's time. In an instant it darts at the tongue, and maintains so cruel a grip, that by and-by the heifer sinks to the ground at the mercy of its ene-mies. The above-named renowned traveller also mentions an astonishing instance of vitality displayed

by a condor which some Indians at Riobomba had taken alive. They first strangled it with a lasso and be lawful for the grantor to enter and discharge him off his office.—Condition precedent is when a lease or several minutes; yet scarcely was the lasso removed the lessee pay to the lessor a certain sum at such a day, then he shall have the fee-simple. In this case, then condition precedes the estate in fee, and on performance thereof gains the fee-simple. The same rule, the condition precedes the estate in fee, and on performance thereof gains the fee-simple. The same rule, the condition precedes the estate in fee, and on performance thereof gains the fee-simple. The same rule and the entered its body, and wounded it in the neck, the condition of the condition subsequent is when a man grants to another his manor of the ground, it did not die of its wounds for half an another lis when a man grants to another his manor of the condition on the same rule is the property of the ground, it did not die of its wounds for half an another lis when a man grants to another his manor of the condition of the condition of the ground, it did not die of its wounds for half an another list when a man grants to another list manor of the condition of the conditio

### Condottieri

its eggs, which are three or four inches in length, and use eggs, which are three or four indices in length, and parfectly white, on the bare rocks. Broderip relates that he saw an egg laid by one of the pair confined in the Zoological Cardens. It was on the bare naked door of the prison. There was no appearance of a nest of any kind. The hen condor does not appear to have exhibited any inclination to sit on her egg, so the next one that was laid was put under a Dorking fowl. The result was successful; but the issue, a male condor, only lived three weeks.

The result was auccessin; but one issue, a marcolardor, only lived three weeks.

Condottient, kon dot-te-air'-e, an Italian word, signifying captains, chiefs, or leaders, but generally endoyed to designate soldiers of fortune, who raised troops of cavalry and infantry at their own expense, and engaged their services as mercenaries with govern-ments or princes. They were numerous in the 14th and 15th centuries in the Italian wars. Sir John Hawkwood, an Englishman, was one of the earliest and most famous in Italy about the reign of Edward III. The troops under the command of the conduttieri were well armed and equipped. In many cases the leaders had considerable military skill, but as their bands only fought for hire, the chief endeavour was not to slaughter but to take prisoners and obtain ransoms. The invasion of Italy by the French, under Charles VIII., put an end to these bloodless fights, by bringing more serious warfare on the field. Although many conductioni obtained great honour and wealth, only one attained high rank,—Francesco Sforza, ori-ginally a peasant. In 1451 he constituted himself duke of Milan, and transmitted the sovereignty to his descendants.

CONDUCTOR (from Sp. conducir, to lead), in Mus. one who superintends everything connected with a concert, and who also directs the performance of s hand or orchestra. His duties are extremely operous. hand or orchestra. His dutics are extremely operous, as they do not consist only (as some people imagine) in the use of his bâton, or in his performance, either as a soloist or necompanist. Indeed, any person who wishes to become a good conductor must possess such a variety of qualities that are rarely found in one man. Some of these qualities we have enumerated below:—1. It is absolutely necessary that he who wishes to succeed as a conductor must be a composer in the full acceptation of the term. 2. He must possess a knowledge of the world as well as of music, and unite great firmness with a strong determination of purpose. 3. He must have a theoretical us well as a practical knowledge of every piece performed.

4. He must have a quick ear, rendered in the highest degree acute by culture, in order to enable him to detect the slightest error at rehearsal. 5. He must be endowed with a most delicate perception of the measure of time and the play of rhythms, so that he may indicate the tampos with accurate division and decision; he must not beat time like a machine, nor yet in so extravagant or violent a manner as to divert the attention of the audience from the music to the eccentric gyrations of his spasmodic below. 6. He must slee be able to accompany, at the shortest notice, on the pianoforte, all kinds of pieces in all kinds of keys, in order to suit the different singers. All this, and much more, is required of a person who aspires to the important office of musical conductor.

CONDUCTORS AND NON-CONDUCTORS OF ELECTRI-CITY, kon-dukt'-ors, terms applied to substances according to whether they receive and communicate electricity readily or not. When a rod of metal is made to touch the prime conductor of an electric machine after it has been charged, all the electricity passes through the rod and through the body of the passes through the rod and through the body of the experimenter into the ground. The metal in this case is said to be a conductor. If, however, a rod composed of glass or shell-lie is used, the electricity will not be carried off. In this case the glass or shell-lie is said to be a non-conductor. All substances conduct electricity in the same manner from metals to lac and gases, but in different degrees; and the term non-conductor only signifies that the substance has a very low power of conducting. In frictional electricity, the best conductors are the metals; after which come graphite, \*\*See-water, spring-water, and rain-water. Ice is a worse conductor than fluid water. Alcohol, ether, paper, dry wood, and atraw are also inferior conductors. Among the substances reckoned as non-conductors. Cone

ductors are shell-lac, amber, resin, sulphur, glass, silk. wool, hair, feathers, &c. In galvenic electricity tricity in a feeble manner are almost, if not altogether, non-conductors; and the metals which are nearly alike in conveying frictional electricity differ widely in their powers of cenveying that obtained from the galvanic battery. When heated, the conducting power of metals is weakened; but in nearly all other substances the effect of heat is to increase the power of conduction. Shell-lac, wax, amber, and sulphur become conductors when fused; and glass conducts readily at a red heat. A conductor is said to be insulated when it rests upon non-conducting supports. In electrical apparatus glass is the non-conductor most employed. It requires to be kept very dry, as any moisture on its surface weakens its insulating power. The discovery of the identity of lightning and electricity has not been without its practical results; amongst which may be reckoned the application of lightning conductors to reckoned the application of tighting conductors to buildings and ships. For buildings, Franklin's original proposition is that generally adopted. It consists in erecting a continuous metallic rod by the side of any building. The rod is pointed at each end, and extended above the highest part of the place to be protected at one extremity, the other penetrating deep into the one extremity, the other penetrating deep into the earth, or in contact with water. The highest point of the rod is generally made of copper, which does not rust. Iron points are very liable to acquire a coating of rust, which is a non-conductor, and diminishes their efficacy. The best conductors for ships are the fixed conductors recommended by Sir W. Snow

CONDUIT, kon'-dit (Fr. conduit; Lat. conducere, to lead along), the name more especially given to any small artificial channel or watercourse, by which water is led along from one place to another. When the conduit is large enough to allow the passage of barges conduit is large enough to allow the passage of barges throughout its length, it is called a canal. (Rec Caral.) The name was also formerly given to plain or ornamental buildings, similar to the drinking fountains of the present day, and provided with any or open pipes, whence water could always be procured. Conduits may be open or closed, when open, they are often called "leats," and the mode of structure adopted is the form used for cutting canals. When closed, they are canarily make of brickwork and circular in above are generally made of brickwork, and circular in shape, or flat at the bottom, with an arched covering above In constructing a close conduit for the conveyance of water for drinking, care should be taken to make the brickwork impermeable to water, that no impurities

may make their way through, and affect the water.

CONDYLURA, kon-di-lu-ra (Condylura cristata), a small insectivorous animal of mole-like appearance, found in North America. It is about four inches and a half long from nose to rump, and has a bushy tail more than three inches long. Its head is remarkably large, body thick and short, and nose rather thick, and the control of the and projecting beyond the mouth. At the end of the nose is a flat star-like process composed of seventeen cartilaginous points. These animals do not make such hills as the European moles, but only little subterraneous walks in the fields, forming banks about four inches broad by two inches thick, and which give way when trod on.

CONE, koun (Fr. cone, Gr. konos), in Bot., a collec-

tive more or less clongated fruit, composed of a number of indurated scales, each of which bears one or more naked seeds. The fruit is seen in the fir, larch, spruce, araucaria, and many other plants of the nat. ord. Conifera. A peculiar modification of the cone is seen in the cypress and in the juniper, and is termed the

CONE AND GALBULUS.

Gulbulus. It differs from the true cone in being more or less rounded in form, and in having the heads of the scales greatly

5/7

Cone

enlarged. In the galbulue of the juniper the scales are fleshy, and are united together into one mass, so that it resembles at first sight a berry. The figures represent the fruits of the Scotch fir (Pinus sylvestris) and the oppress (Cupressus semperatures).

Cors., in Geom., denotes a solid body, which terminates in a point and has a circle for its base. The axis of a cone is a straight line drawn from the apex to the centre of the circle forming the base. When the axis is prepared in the player of the hase the cone is is perpendicular to the plane of the base, the cone is said to be right; and when the axis is inclined to the plane of the base, the cone is said to be oblique. A transacted cone is the lower part of a cone cut by a plane parallel to the base. The area or surface of a plane parallel to the base. The area or surface of a right cone, exclusive of the base, is equal to a triangle, the base of which is the periphery, and its height the alant side of the cone, or equal to the sector of a circle whose radius is the slant side, and its are equal to the circumference of the base of the cone. Every cone, whether right or oblique, is equal to one-third part of a cylinder of equal base and altitude: the solid contents are therefore found by multiplying the base by the altitude, and taking one-third of the product. The centre of gravity of a cone is in the axis, at a distance from the centre of the base equal to one fourth the distance from the vertex. (See Conic Sections.)

COMEDERACY, kon-fed'-er-d-se (Lat. con, together;

fadus, a league), a term in politics signifying an alliance of independent states for a common object. It is sometimes employed, but less properly, to the alliance of individuals. (See Constituent)

CONFEDERATION OF THE RHINE, kon-fed-er-ai'-shun. -During the war between France and Austria, in 1805, several German princes, feeling that they were too weak to remain neutral, were compelled to ally themselves with France. The next year the arch-chancellor announced at the diet that Cardinal Fesch, the uncle of Napoleon, had been appointed as his coadjutor. This proceeding was entirely at variance with the German constitution; but the same year sixteen German princes formally signed an act of confederation, in which they declared that their connection with the Germanic empire was dissolved, and that henceforth they were allied with France. They at the same time tried to justify the course they had taken by pointing out the evils and weaknesses of the Germanic government. Bacher, the French ambassador, at the same time declared that Napoleon no longer recognized the German empire. Several other princes recognized the German empire. Several other princes joined the Confederation of the Rhine, as it was called, during the next two years; and at the close of 1808, a territory, with an area of 122,236 square miles, was under the protectorate of the French emperor. The terrible reverses sustained by the army of France lifted a heavy burden from the German nation, and in the year 1913 they rose and threw off the degrading yoke which they had been compelled to bear. This league terminated with the fall of Napoleon in 1814,

league terminated with the fall of Napoleon in 1813, and was succeeded by the Germanic Confederation.

CONFEDERATION, THE GREMANIC, kon-fed-er-ai-shun, the federal union of the sovereign princes and the free towns of Germany. It was formed at the congress of Vienna in 1815, and was framed to supply the want of the ancient imperial government dissolved. in 1808. As originally settled, Germany was divided into forty sovereign states, or portions of states, but the number is now reduced to thirty-five. The diet is the number is now reduced to thirty-five. The diet is fifteenth or sixteenth year. The person confirmed formed by plenipotentiaries, and is permanent; it reforms the representative body of the league, and six at Frankfort-on-the-Maine. When the confederation meets as a general assembly, six of the states—Austria, Frussia, Bayaria, Saxony, Hanover, and Wurtenburg—have four votes each; five other states, three seach; four, two; and the rest one. In the formation of fundamental laws, admission of new members into the confederacy, and on religious questions, unanimity is required. The votes in the ordinary assembly are so importioned as only to make seventeen in all, as it would be manifestly unfair if the votes of the smaller states were of equal force with those of the greater. The ordinary diet manages the general affisirs of the confederation. Austria presides in both diets; but each states are offer its propositions, and the president in ordinary diet manages the general affisirs of the confederation. Austria presides in both diets; but each state or its plant or sixteenth year. The person confirmed in fifteenth or sixteenth year. The person chairs and work in their place.

Confirmation or sixteenth year. The person confirmation of the consequence in the confidence in their place.

Confirmation or disable that their place.

Confirmation or disable the baptismal vows in their place.

Confirmation or disable the supplies their place.

Confirmation or disable the supplies their place.

Confirmation or disable the baptismal vows in their place.

Confirmation or disable the baptismal vows in their place.

Confirmation or disable the baptismal vows in their place.

Confirmation or disable the person that

### Confiscation

federal act, a large army, the peace establishment of which consists of 120,000 men. In case of war, the states are bound to furnish troops to the field in the proportion of one in the hundred of the population.

CONFERVOIDE, kon-fer'-toy-de, in Bot., a sub-ord. of

the Alga (which see).

Confession, kon-fee'-shun (Lat. confileor, I acknowledge), in Theol., is the verbal acknowledgment which a penitent makes of his sins to God or to a fellowcreature. Among the Jews, it was the custom on the annual feast of expistion for the high priest to make confession of sine to God, in the name of the whole people. Besides this general confession, the Jews were enjoined, if their sins were a breach of the first table of the law, to make confession of them to God; but violations of the second table were to be acknowledged to their brethren. Confession seems to have been to their Deterrent. Concession seems to have been early introduced into the Christian church; but at first it took place openly, and was chiefly in the case of such as had apostatized themselves or been guilty of any flagrant offence, and were desirous of being readmitted into the Church. The practice of private or aumicular confession seems to have gradually crept in about the 5th century; and Innocent III., in the fourth Lateran council (1215), made it obligatory on every adult person to confess his sins to a priest at least once a year. The person confessing is allowed to conceal no sin,—at least no mortal sin,—that he remembers to have committed and not to have already confessed, and the father confessor is bound to perpetual secrecy. Confession obtains also in the Lutheran church, but with this difference, that while in the former case it is obligatory, it is here only recommended as a means by which a contrite sinner may obtain advice and consolation.

Confussion, in Law, is where a prisoner indicted of an offence, and brought to the bar to be arraigned, upon the indictment being read to him, and the court demanding what he can say thereto, he confesses the offence and the indictment to be true. fession, in civil cases, is where the defendant confesses the plaintiff's right, or, in prosecutions under penal statutes, by which confession there may be a mitigation of a fine against the penalty of a statute, though

not after a verdiet.

CONFESSION OF FAITH, is a formulary detailing the articles of faith held by any particular church, most ancient of these are what are known as the Apos tles', Niceue, and Athanasian creeds. The Church of Rome, while receiving these, had no fixed and authoritative confession till the council of Trent. A summary of the doctrines contained in the canons of that council is given in the creed published by Pius IV. (1564) in the form of a bull. The numerous other confessions will be found coticed under their respective heads, or under the names of the different sects to which they belong, in other parts of this work.

CONFIRMATION, kon-fir-mai'-shun (Lat. confirmatio, strengthening), in an ecclesiastical sense, denotes the ceremony of laying on of hands in the admission of baptized persons to the enjoyment of church privileges. In the early Church, this ceremony appears to have been performed immediately after baptism; but afterwards a delay of about seven years came to be interposed after infant baptism. The present practice in the Church of England is to delay it until about the fifteenth or sixteenth year. The person confirmed fifteenth or sixteenth year. The person confirmed releases his godfather and godmother of their obliga-

# Conge d'Elire

offence,—are bone configurate, so we say of those which are forfeited to our crown, or the queen's exchequer, for any offence which causes or works a forfeiture.

Cones n'Eller, koan (a) jhay de(r) leer (Fr., leave to choose), is the king's license or permission sent to a dean and chapter to choose or elect a new bishop

when a bishopric becomes vacant.

Congriation, kon-jel-ai-shun (Lat. congelo, Ifreeze), the process of passing from a fluid to a solid state, whether through the effect of pressure or the lowering of the temperature. Until lately, the latter cause was held to be the chief reason of congelation. It is now very apparent that temperature is only one element.

very apparent that temperature is only one element. Water may be cooled many degrees below 32° Fahr., and yet retain its liquid state. (See ICE.)

CONGER EEL, kong'-qur (lat. anguilla conger).—This fish may easily be distinguished from the fresh-water species by the upper jaw being the longest, and the dorsal fin commencing much nearer the head. On account of this difference, Cuvier separated them from the rest as a sub-gen. It is durker on the upper parts than the common cel, and brighter beneath. It attains a very large size, weighing occasionally from seventy to a hundred pounds, and measuring six and eight feet in length. The principal conger-fishery is on the Cornish coast. The fishing takes place at night (the darker nish coast. The fishing takes place at night (the darker the more chance of success), and the ordinary bait is a pilohard. "It is dreadfully voracious," says Mr. Couch; "it spares not even its own species. From the stomach savs Mr. Couch : of a specimen weighing twenty-five pounds I took three common dabs, and a young conger of three feet in length. The power of jaw in this fish is very great; in the stomach of small specimens examined on the coast I have found the young testaceous coverings of our shell-lish comminuted into fragments. They are often tempted by the crustacea entrapped in the lobsterpots to enter these decoys in order to feed on them,

and are thus frequently captured."

CONGESTION, kon-jest'-shun (Lat. congestio, from congero, I amass), is a term employed in Med. to denote an unnatural accumulation of blood in the capillary vessels of any part, accompanied with dis-ordered function of the organ in which such accumulation takes place. The organs most liable to congestion are the brain, lungs, and liver; but other parts are also subject to it. It is usual to distinguish two kinds of congestion,—a passive and an active. In passive or simple congestion there is merely an accumulation of blood arising from distension and diminished vitai energy in the capillaries; in active congestion, on the other hand, the blood-vessels are in a state of inordinate activity, and a preternatural quantity of blood is determined to them. Anything may be the cause of concertion which diminishes the vital energy of the capillaries, or which increases the quantity of blood which they contain. (See INFLAMMATION.)

CONGLOMERATE, kon-glom'-e-rait (Lat. con, together glomerare, to gather in round heaps), in Geol., a rock composed of rounded and water-worn fragments of stone, bound or cemented together by silicious, ferruginous, or calcarcous matter. The component frag-ments may vary from pebbles the size of a pea to boulders half a ton in weight. Some conglomerates are commonly known as pudding-stones, from the resem-blance of the pebbles in the mass to the fruit in a plum-midding.

plum-pudding.

kon-gre-gai'-shun (Lat. con, CONGREGATION, grex, a flock), commonly signifies an assembly of persons met together for the purpose of religious worship. In the Roman Catholic church it is applied to certain boards of cardinals, prelates, and others intrusted with the management of particular branches of the affairs of the Church. There are twenty-one of these congregations, fifteen for spiritual and six for temporal purposes; the chief of them being the Congregation de Propaganda Fide, for consulting as to the advance-ment of the Catholic religion throughout the world; the ment of the Cashole religion throughout the world; the Congregation of the Index, for examining books, and deciding upon their fitness for general perusal; the Congregation of Sacred Rites, for regulating all matters relating to ceremonies and rites in worship; the

# Conifere

Discipline; and the Consistorial Congregation. These congregations act as a check to the power of the pope; for, though their proceedings are usually sanctioned by him. he cannot put a veto upon them without weighty reasons. A company of monks or religious persons, forming a subdivision of an order, is also called in the Church of Rome a congregation. If The called in the Church of Rome a congregation. "The Congregation of the Lord" was a title assumed by the first Scotch Presbyterian reformers, in contradistinc-tion to the Church of England, which they called the "Congregation of Satan." They appeared first in 1557 under the duke of Argyle, and at a later period were led by John Knox.

CONGERGATIONALISTS. (See INDEPENDENTS.)
CONGERSS, kon'-gress (Lat. congresses), a meeting of
the rulers or representatives of different states, for the purpose of considering matters of international interest. Although the term is not used in this sense at the present time in America, it originally had this significa-tion. The first congress held in America was a meettion. The first congress held in America was a meeting of the delegates of the various British colonies, to consider their grievances, in 1765. Before a treaty of peace is signed, there is usually a meeting of plenipotentiaries, which is called a congress. The term is, however, more strictly applied to those great diplomatic conferences where extensive schemes of future policy are determined upon. The congress of Vienna, held in are determined upon. The congress of Vienna, held in 1815, at the conclusion of the great war, is one of the most famous, and also the congress of Carlabad, held in 1819, for regulating the affairs of Germany; the congress of Paris, held in the year 1856, at the conclusion of the Crimean war, had for its purpose the consideration of the relations between Russia and It is the most important congress of the day. The national legislature of the North Turkey. present day. American states is called the Congress in the constitu-tion of the general government. It consists of a Senate and a House of Representatives, each constituting a distinct and separate branch. The term congress a distinct and separate branch. The term congress has also been applied in late years to any philanthropical meeting on a large scale, in which the representatives of different nations have appeared; such as the Peace Congress, the Social Science Congress.

Congruity, koing-rai-cele (Chat. congruo, I come together, correspond, or agree), denotes a suitableness or relation of agreement between different things. Congruity, wherever it is perceived, is agreeable, agreeable, and is so nearly allied to beauty as to be commonly regarded. as a species of it. It is difficult to define what the nature of this relationship is, or to ascertain what are the particular objects which, taken in conjunction, manifest congruity; for there are many objects that suggest neither congruity nor incongruity. Incongruity, on the other hand, is an unsuitableness between

gruity, on the other hand, is an unsuitableness between different things, and is disagreeable.

Conic Sections, kon'-ik sek'-shuns, the curves formed by the intersection of a right or oblique cone and a plane. If the cone is cut by a plane parallel to the base, the section is a circle; if the section is made obliquely, that is, nearer to the base at one end than the curve of the control of the large of the control of the large of the control of the large o the other, a curve is obtained which is called an ellipse; if the section is made parallel with the axis, perpendicular from the vertex, or so as to make a greater angle with the base than is made by the side of the cone, the curve obtained is called a hyperbola; and if the section is made parallel with one side of the cone, the curve is called a parabola. The ancient Greeks investigated the properties of conic sections with great acuteness; and a work on them is still extant, written by Apollonius of Perge.

CONIFER, ko-nif'-e-re (Gr. konos, a cone; Lat. fero, I bear), in Bot., the Pine fam., a nat ord. of dicotyledonous plants, in the division Gymnosperma,—resinous trees, or overgreen shrubs, with branched continuous stems. The leaves are needlebranched continuous stems. The leaves are needle-shaped or lancolate, parallel-veined, fascicled, or imbricate. The flowers are naked (without floral envelopes), and monecious or discous, the male flowers being arranged in deciduous amenta, and the female flowers in cones. The fruit is either a cone or ters relating to ceremonies and rites in worship; the a galbulus. The seeds are naked, hard externally, and Congregation of Relics, for inquiring into the genuine- ness of sacred relics; the Congregation of the Holy Office, or Inquisition, for taking cognizance of heresies occur in cold and tropical regions. There are about and all novel opinions; the Congregation of Religious 30 genera, which inquide about 120 known species.

#### Contain

They possess very important properties; many supply valuable timber, and mast of the species contain an elec-resinous juice, or turpentine, which is composed of a relatile oil and resin. (See Arks, Pinus, Just-PREUS, CEDRUS.)

CONIUM, ko'-ne-um, in Bot., the Hemlock, a gen. plants belonging to the nat. ord. Umbellifera. I most important species is C. maculatum, an indigenous plant, which is extensively employed in medicine to retirev pain, relax spasm, and compose general nervous irritation. It owes its properties chiefly to the presence of a colourless oily liquid, with a penetrating mouse-like odour, to which the name of Conic has been given. In improper doses hemlock is a powerful poison, and many latal accidents have arisen from the having been mistaken for humiless umbelliferous claste; it may, however, he readily distinguished by the botamical characters. The stem is large, round, its botanical characters. The stem is large, round, and smooth, with spots upon it of a purplish-black colour; the leaves are dark green, and shining; the general involucre consists of from three to seven leaflets, the partial involucre of three leaflets; the fruit has undulated, crenated primary ridges, and contains no sitts; and the whole herb, when bruised, evolves a disagreeable smell, which has been likened by some to that of mice, and by others to that of cat's urine. No chemical antidote is known for hemlock.

CONJUGAL RIGHTS, kon'-ju-gal (Lat. con, and jugo, I yoke) .- A suit for restitution of conjugal rights is a species of matrimonial causes, and is brought in the Court of Divorce whenever either the husband or wife is guilty of the injury of subtraction, or lives separate

from the other without any sufficient reason.

CONJUGATION, kon-ju-gai'-shun, in Gram., is a regular distribution of the several inflections of verbs into their different voices, moods, tenses, numbers, and persons. (See Veeb and Grammar.)

CONJUNCTION, kon-junk'-shun (Lat. conjungere, to join together), in Astron., when two heavenly bodies have the same longitude or right ascension (see ASONNSON, KIGHT), they are said to be in conjunction. If they also had the same declination, or latitude, north body would apparently cover the disk of that which is more remote. When any heavenly body is in a line between the earth and the sun, it is said to be in conjunction with the latter; but it is said to be in opposition to it when the earth comes between the body in question and the sun. Geocentric conjunction is the conjunction of two heavenly bodies as viewed from the earth; but when heliocentric conjunction is spoken of, the conjunction is understood to be considered as if viewed from the sun. True conjunction is the observation at the earth's surface reduced to what it would be if witnessed from the centre of the earth.

CONJUNCTION, in Gram., is an indeclinable word or particle which serves to unite words, sentences, or clauses of a sentence, and to show their relationship or dependence upon one another. There are two kinds -the conjunctive and the disjunctive; of ocujunctions,—the conjunctive and as, Peter and John, James or Robert.

CONJUBATION, kon-ju-rai'-shun (Lat. con, and juro, I swear), is the act of using certain words or ceremonies to obtain the aid of a superior being, more particularly applied to the magical words, characters, or ceremonies, by means of which evil spirits, tempests, &s., are said to be raised or driven away. The Romish priests formerly affirmed that they could exper devel by hely water prepared in a particular manner, and aprinkled over the postessed person, with a number of conjurations and exorcisms. According to some authors, the difference between conjuration and witcheraft is, that in the former case the effect is accom-plished by prayers and invocation of God's name; whereas in the latter it is brought about by supplicating the aid of the devil.

CALIBY THE BIG OF THE GEVIL.

CONNOISEEUR, kom-noy-sure' (Fr. connoiseeur, from Lat. cognoscere, to know), a person who is skilled in any subject, and particularly one who is well fitted to judge of the merits of paintings and soulpture, from possessing a critical knowledge of works of art.

### Conscience

given to the invasion of England by William of Normandy, who, having overcome Harold II. at the battle of Hastings (15th Oct. 1086), obtained the crown of England, and became the founder of the Norman dynasty.

CONSANGUINITY, or KINDRED, kon-san-guin's-te (Lat. consanguinitas), is the connection or relation of persons descended from the same stock or common (See COLLATERAL CONSANGUINITY, and ancestor. LINEAL.

CONSCIENCE, kon'-shens (Gr. suneidesis, Lat. con scientia, Fr. conscience, Ger. gewissen), is a term applied to the moral nature of man in general. According to its ancient usage among the Latins, the word conscientia was primarily applied to being privy to, together with another; and in its secondary meaning it bore a moral signification, or knowledge of one's own conduct, whether right or wrong. The modern use of the word is more extensive in its sense, denoting not only what the Latin moralists signified by it, not only the sense of the difference between right and wrong in our own and others' conduct, but containing likewise the important element of the feeling of human responsibility. Thus conscience, as it is at present accepted, is not only applied to the moral judgment which accompanies all moral actions, as to whether they are right or wrong, but it denotes, besides, that feeling of approbation or disapprobation, of rectitude or contrition, which invariably accompanies all moral actions. Thus a judgment and an emotion lie at the root of what is known as the conscience; for not only are men accustomed to say, "My conscience cannot approve of such and such conduct," but they likewise own to being disturbed by certain "qualms of conscience" on occasion of any violation of rectitude either in their own or in others' experience. Thus conscience and the moral faculty mean almost the same thing; although the former, as it is unques-tionably the more ancient term, so it seems to be the one which is ordinarily employed in common conversation instead of its heavier and more learned rivals of the moral sense, the moral nature, and so forth. Nearly all writers are agreed as to the existence of some sort of a conscience in human nature, whether or not they are prepared to subscribe to the moral faculties, and moral senses, and moral natures of other writers. Thus Adam Smith, who is a strong advocate for sympathy, as the ultimate explanation of our moral nature, is loud in his proclamation of the existence of conscience Sympathy, indeed, is with him the ultimate resolution which he gives to the popular conscience. And Dugald Stewart deplores the employment of such metaphorical language as "this man in the breast," of Adam Smith, instead of what he considers as the more appropriate terms of conscience and reason. (See Stewart's Collected Writings, Active and Moral Powers, vol. i. p. 333.) Smith, in his Theory of Moral Sentiments (part vis. 2., c. 3), says that the conscience "properly signifies our consciousness of having acted agreeably or contrary to the directions of some moral familts." And Dureald the directions of some moral faculty. And Duvald Stewart (l. c.) adds, "The truth I take to be this, that the word conscience coincides exactly with the moral faculty; with this difference only, that the former refers to our own conduct alone, whereas the latter is meant to express also the power by which we approve or disapprove of the conduct of others." But this seems a somewhat arbitrary limitation of the term conscience; and in this article it is made throughout to apply both to our own moral conduct and to that of others. ethical philosopher, of course, is bound to inquire into the nature of the distinction between right and wrong in human conduct, and into the complexion and character of those feelings with which right and wrong are contemplated by man; but conscience, in so far as it is a portion either of ethics or of the practical conduct of man, merely requires to ascertain that there is such a principle as right and wrong in human nature, and that there are such feelings as those of responsibility to judge of the merits of paintings and sculpture, and of remores, which approve or disapprove of human from possessing a critical knowledge of works of art. It may be considered as equivalent to the vulgar term "knowing one" used on the turf. In the Italian, entering the most substitution of morality which may be held, the inquirer anch a person is termed cognoscente.

Conquest, The, kong-kwest in Hist., is the name little trouble. Suffice it to say, that this principle in

### Consciousness

human nature has been analyzed into a judgment and an emotion; one gives himself little anxiety as to the ultimate origin of this judgment, or as to the fine elements of which this affection may be composed. The unrepented pleasure, accordingly, of Socrates; the variously modified views of human happiness of Plato and Aristotle; the mere reverence for morality or bare acts of duty of the Stoics; the pleasure theory of Epicurus and his school; the human will and the of Epicurus and his school; the human will and the divine will of the schoolmen; the greatest happiness principle of Bishop Cumberland, of Jeremy Bentham, and of the two Mills; the rational views of Cudworth and of Price; the eternal fitness of Clarke; the moral sense of Shaftesbury and Hutcheson; the refined view of the selfish system of Leibnitz; that love to being in general of Edwards; the principle of reflection or conscience of Batler; and a class of desires and affections having disregations and volitions for their affections, having dispositions and volitions for their object, of Mackintosh: these, we say, are all views more or less precise, more or less closely allied to the truth of the real theory of our moral nature, be it what it may. We may remark in general, that of all speculators, Bishop Butler was undoubtedly the first to point out the supreme authority of conscience in the moral constitution of man. Although the ancient moralists had beautifully described the result of such a state of matters as Butler pointed out as the abiding law of our nature, and while Lord Shaftesbury and Francis Hutcheson laid much too little stress on this unquestionably the first to point out an important dis-tinction, which has, since his time, been adopted by all moralists. It accordingly appears that this moral faculty or conscience is the supremely regulative principle in our constitution. Give the laws which govern its activity free scope, the most beautiful harmony and propriety of conduct will ensue; violate those laws, and the direct confusion in character and in conduct is the result. (See Stewart's Active Powers and Mackintosh's Ethical Philosophy, and the other writers

Mackintosh's Ethical Philosophy, and the other writers alluded to in this article.)

Consciousness, kon'-shus-ness (Gr. suneidesis, Lat. conscientia, Fr. conscience, Ger. becausetseyn), is the recognition by the mind of its own acts. While it is thus a comprehensive term for the complement of all our mental energies, it nevertheless, from its high generality, cannot at all be defined. It is so elementary, that it is impossible to resolve it into any notion more simple than itself. But while consciousness cannot logically be defined, it may still be philosophically analyzed. The forms under which this condition of all The forms under which this condition of all thinking operates, are—I know that I know, I know that I feel, and I know that I desire; or, in other words I am conscious that I know, feel, and desire. And while this is so, the act necessarily involves, (1) a knowing mind, (2) a know object, (3) a recognition by the mind of its object. It accordingly appears that consciousness and knowledge mutually involve each contact they are not opposed as really diverse. It is somewhat remarkable, that a term in all ways so important and convenient should have escaped the subtle Greeks and the rhetorical Latins, and that it should have been reserved for Descartes, a Frenchman, to introduce the term conscientia, or consciousness, in its modern signification. An instance or two of the modern use of the word may, no doubt, be found in Quintilian and the Latin fathers; but no consistent adoption of it is to be met with before the time just specified. Among the Romans, if two individuals or more had a common knowledge of some circumstance. such a knowledge was called conscientia, or (con-scio) knowledge together with; but, except this, the term was always employed in a moral sense, as equivalent to our word conscience. The general conditions that attach to consciousness, in its modern acceptation, are obvious and palpatle:—1. That the knowledge which it obvious and palpable:—1. That the knowledge which it implies is actual, and not merely potential. For example, if I say of my friend that he knows the shape of the reading-room in the British Museum, that it is round, and not square, I mean that he is not conscious of the fact at the present moment, but that he may be rendered conscious of it by having his attention drawn to the circumstance. We are, in truth, conscious only of the present. 2. The knowledge which it implies is immediate, and not distant. Thus, while I am con-

# Conscription

scions of the dome of St. Paul's while I look at it, I am unconscious of it when it is out of my mind, having to ransack the arcans of memory to bring it up into consciousness as often as I wish to recall it. Again the 3rd place, I am only conscious in so far as I Aguin, in conscious of some definite object, as contrasted either with no object, or with another object different from the present one in its qualities and modifications.
Thus, suppuse I am conscious of the desk at which I write, I am only so as taking the present desk in contrast with some other supposable desk, such as the one at the British Muscum, at which many men ar accustomed to write at the same time. In the 4th place, there is always judgment in every act of con-sciousness, or the affirmation or negation of one thing being or not being, having or wanting the qualities of another. We cannot, in truth, discriminate without judging; so that this fourth condition might stand as a corollary to the third. Every act of mind, in fruth, implies a judgment, as every act of consciousness implies an act of affirmation or negation. The 5th undeniable act of consciousness is memory; for I can-not be conscious of an object without discriminating it from another state of mind to which the present one was only a successive phenomenon. I must distinguish all the separate acts of consciousness, and I can only distinguish them by the aid of memory, as I can only discriminate them by the help of judgment. As the fourth condition of consciousness, this one holds the position of being a second corollary to the third. Hutcheson, Reid, and Stewart, expose themselves to criticism by affirming this faculty to be special in its operation, and not general. They affirm, in short, that it is possible to read a book, and to know that we have read it, without being conscious at the same time of some portion of its contents; nay, that it is possible to be conscious of the perception of a book without being aware that it is a book that we perceive. There can only be a system of philosophy in so far as the veracity of consciousness is implicitly or explicitly affirmed by it. Philosophy, accordingly, in asserting affirmed by it. Philosophy, accordingly, in asserting its own possibility, asserts, in the same breath, the truthfulness of consciousness. Leibnitz truly has remarked, in his Nouveaux Essais (lib. ii. c. 27, s. 13), that "if our immediate internal experience is not certain, there can be no truth of fact of which we can be assured. All speculators agree in this, both sceptical and dogmatical. But not only is consciousness the evidence and authority of all legitimate speculation, it is likewise the source and spring from which it flows. As the criterion of philosophy, it must be clear and unadulterated; and hence there emerge three great laws that regulate its legitimate development. These are,—lst, that it be charged with no fact but what is simple and ultimate; 2nd, that all the facts ascribed to consciousness be taken without reserve in coming to any conclusion; and 3rd, that nothing but the facts, or what these data imply, be accepted as legitimate in any process of inquiry. As one illustration of the fertility of accepting or of rejecting these leading laws, may be mentioned the circumstance, that on the duality or unity of the first fact of consciousness hangs altogether the entire system of speculation which any inquirer may adopt. If, in saying that I perceive a stone, I do not recognize that there are two independent objects in this act, my perceiving mind, and the stone which I perceive, as two separate independent existences, but maintain with Berkeley and Fichte and Ferrier, that what seems a stone is not really a stone, but only a mode of my mind or of some other mind, then I deny the duality of the substances and assert their unity. And if I do so, I deny the doctrines of realism and accept those of idealism, and, possibly, of partheism. We have only spoken of the partial rejection of the veracity and integrity of the facts of consciousness; something might also be said on the total rejection of those facts, which leads to the specu-lative dootrines of nihilism at the first remove.—(For further illustration on this point, see Reid's Works, by Sir William Hamilton, p. 748.)
CONSCRIPTION, kon-krip'skun (Lat. conscribere, ta

enrol), the name given to the compulsory system of enlishment of soldiers for the army, practised in France. and other foreign countries. Every Frenchman, as soon as he attains the age of 20, is liable to be drawn

### Consecration

Consols

by lot to serve in the ranks for seven years, unless he be incapacitated by any bodily or mental infirmity, or exempt, from being the only sen of a widow, or the eldest son of a family that are left without parents. Pupils at college, and those who are studying for the church, are also exempt, as well as those who have a brother already in the army; and no man is taken at present who is under 5 feet 2 inches in height, although during the Penineular war, the standard height in the French army was only 4 feet 11 inches. In France about 200,000 yearly attain the age of 20, and become hable for service. Those who are exempt from any liable for service.

cause are not reckoned in this calculation.

CONSECRATION, kon-se-krai'-shun (Lat.), the solemn act of dedicating any person or thing to a divine service or use. In modern times the consecration of men is usually called ordination, and that of temples, churches, attars, &c., is called dedication. Consecration was one of the most universal religious ceremonies of the ancients. It was practised in India, Egypt, Judea, Chaldra, Greece, Rome, among the Celtic Druids of Britain, and in Europe generally. At the commencement of the Mosaic dispensation, all the first-born of man and beast were consecrated to the Lord. Subsequently the whole tribe of Levi were consecrated, and Asron and his sons were especially consecrated to the priest's office. In the Old Testament there is a depriest's office. In the Old Testament there is a description of the consecration of the tabernacle and altar, of the first or Solomon's temple, and also of the consecration of men, beasts, houses, fields, and the walls of Jerusalem. It was not until the commencement of the 4th century, when Christianity, under Constantine, became the religion of the Roman state, that churches were publicly consecrated. The ceremony was then attended with great pomp and splendour.

The practice of consecrating buildings for religious purposes is still continued in the Church of England as well as in the Church of Rome. In the Euglish church the burial-ground is also consecrated.

CONSECRATION OF A BISHOP, is the separating of a person for the holy office of a bishop, by imposition of person for the nony office of a bishop, by imposition of hands and prayer. According to a cannon of the Niceue council, there must be four, or at least three, bishops present at the consecration of a bishop. The ceremony used in the Church of England will be found in the Book of Common Prayer: it was prepared in the reign of Edward VI. It is stated in the preface, that "no none shall be accounted or taken to be a bishop, or suffered to execute the same function, unless he be called, tried, and admitted thereunto, according to that form, or hath had formerly episcopal consecration." The Church of Rome denies the validity of the English rae church of home denies the validity of the rights orders generally, as derived from heretical and improperly-consecrated bishops. An old story, refuted by Lingard, a Roman Catholic historian, is known by the name of "the Nag's Head Consecration." It is asserted that Archbishop Parker was consecrated at the Nag's Head the Nag's have of the Particle Parker was consecrated at the Nag's the Nag's the Particle Parker was consecrated at the Nag's the Na head tarendshop ranker was consecrated at the Mag s. Head tavern, Cheapside, by one of the Protestant bishops laying a Bible on his head, and saying, "Take thou authority," &c. According to Lingard, the whole story was false, as Parker was consecrated by the bishops of Bath, Chichester, and Exeter, at the chapel at Lambeth. The bishop of Bath had been consecrated according to the Roman Catholic pontifical, in the reign of Henry VIII. The story probably arose from the fact that the commissioners who ratified Parker's election dined at the Nag's Head, a tavern much occu-

pied by country clergymen. Consecuation of Churches.--All churches in this zountry must be consecrated, as the law recognizes no place as a church till it has been consecrated by the bishop. The ceremony was formerly one of great bishop. The ceremony was formerly one of great solemnity and grandeur. During the sitting of the Long Parliament, Alderman Pennington presented a petition, in which the consecration of churches was included among "the manifold cvils, pressures, and included among "the manifold evils, pressures, and grievances caused, practised, and occasioned by the prelates and their dependents." At the Restoration, the practice of consecrating churches, which had been abolished, was resumed, and since that time each bishop has adopted any form he thought best; though, the first of consecrating churches, changles perhaps, the form of conscorating churches, chapels, and burying-places, which was sent down by the bishops to the lower houses of convocation (1712), and altered by a committee of the whole house, is the one

-not that it is enjoined by any competent authority now most generally used.

CONSECRATION OF THE ELEMENTS. (See EUCHA-RIST.)

CONSEQUENCE, kon'-se-quens (Lat. con, and sequor, I follow), is that which follows or results from any cause, act, or principle.—In Log., it is applied to the conclusion of a syllogism, or that which results from the premises.

CONSERVATIVE, kon-serv'-a-tiv (Lat. con, and serve, I keep or guard), in a political sense, is one whose sim it is to preserve from innovation or radical change the existing institutions of the country, both civil and ecclesiustical; and hence he is opposed to such measures and changes as he believes to tend in that

direction. (See TORY.)

CONSERVATORY, kon-ser'-va-tor-e (Lat. conservare, to preserve), a glass house for the reception of tender plants that require protection from the wind, frost, and rain. A conservatory requires a little artificial heat from a stove placed within it in winter only; and this constitutes the chief point of difference between the conservatory and hothouse, which is heated by pipes, and an apparatus for the transmission of hot air, throughout the year, as well as by a bark bed. Con-servatories are often rendered an ornamental feature in a building when attached to it and connected with one of the principal apartments, or forming the entrance.—Ref. Beeton's Book of Garden Management.

CONSIDERATION, kon-sid-e-rai-shun (Lat. consideratio), in Law, is the material cause of a contract, without which it cannot bind the party. The consideration is either expressed or implied. The latter is when the law itself enforces a consideration; as, if a man goes into a common inu, and, staying there some time. takes meat or lodging either for himself or his horse, the law presumes he intends to pay for both, notwithstanding there is no actual bargain or contract between him and his host. Also there is a consideration of nature and blood, and a valuable consideration; and therefore, if a man be indebted to divers others, and, in consideration of natural affection, gives his goods or estate to his son, this is a fraudulent gift us against the creditors (unless it be upon, or in consideration of, his marriage), because this act intends a valuable conaideration.

CONSISTORY, kon-sis'-tor-e (Lat. consistorium), was CONSISTORY, Kon-sur-ore than consistent, coriginally applied, under the later Roman emperors, to the place in which their privy council met, and afterwards to the covacil itself. When the Roman church was established, this form of court was adopted by the ecclesiastical power, and, down to the present time, the highest council of state in the Roman govern-ment is called the consistory. The ordinary consistory, which is composed only of cardinals, and over which the pope himself presides, meets once a week in the papal palace, for the transaction of general business connected with the Church, the election of cardinals, bishops, and the like. Extraordinary consistories, or, as they are called, secret consistories, may be summoned at any time by the pope, as occasion may require. The Protestant churches on the continent have also their consistories, which manage the affairs of the Church. In England the consistory is a spiritual court formerly held in the nave of the cathedral church, or some chapel or aisle belonging to it, in which the bishop presided, and had some of his clergy which the disapp presided, and had some of his clerry for assessors and assistants. This court is now held by the bishop's chancellor or commissary, either in the cathedral church or other convenient place in the diocese for hearing and determining ecclesiastical causes.

CONSOLE, kon'-soal (Fr. console), in Arch., a richlyornamented bracket in the form of a corbel (see Corbert), fastened to a wall to form a support for busts, statuettes, candelabra, &c., or used to support a cornice as a modilion. The name console-table is applied to a semicircular table projecting from the applied to a semicircular table projecting from the wall, and supported on brackets terminating in a solid foot, or fixed to the wall. There are other forms of console-tables, but this is the most common. Consols, kon-sols, a Sontraction of the term Consolidated Annuities. The British government, during the process of borrowing the money which now forms the patient debt in the patient debt in the patient debt.

the national debt, laid themselves under certain special

552

# Consonant

conditions; these conditions generally consisted in an undertaking to pay an annuity of so much per cent. On account of the complication and confusion which on account of the complession and contract which were consecuted in 1737 the Consolidated Annuities Act was passed. By this statute an average of the value of the different stocks was struck, and the whole consolidated into one fund, kept in one account at the Bank of England

CONSONANT, kon'-son-ant (Lat. con, and sono, I sound), in Gram., is a letter which cannot be sounded by itself without the aid of a vowel placed either before or after it.

CONSORT, kon'-sort (Lat. consors, from con and sors, lot), is literally one who throws in his lot with another; a companion or partner in an undertaking; a husband or wife. By the law of England, the queen consort, the wife of the reigning king, is, in all legal proceedings, looked upon as a single, not as a married woman She may purchase and convey lands, grant leases, and do other acts of ownership without the intervention of the king. She may also sue and be sued in her separate person, and possesses courts and officers distinct from those of the king. She pays no toll, and is free from any fine which a court could impose upon women in general; but in other respects she is on a similar footing with the other subjects of the king. In her life and person, however, she enjoys the same protection as the king, it being high treason to design the death of either. The husband of a queen regnant is not endowed by the constitution with any distinctive rights or privileges. All his privileges and honours, therefore, must emanate from the crown under the form of warrant, grant, patent, &c., or else be con-ferred by act of parliament introduced after a royal message on the subject. Up to 1857, when the title of Prince Consort was bestowed upon him by letters patent, the late Prince Albert possessed no distinctive title and no place in court ceremonial but such as was accorded to him by courtesy.

Secorded to him by courtesy.

CONSTABLE, Expl-skli-bl (Old Fr. connestable; Sax.

cuning or cying, and staple, the stay or hold of the king;

Lat.comes stabult, literally, head of the stables), an officer

who supports the queen by the maintenance of her

peace. The office of lord high constable has been disused

in England, except only upon great and solemn occa
sions. Such as the coronation and the like, ever since sions, such as the coronation and the like, ever since the attainder of Stafford, duke of Buckingham, under King Henry VIII.; as in France it was suppressed about a century after, by an edict of Louis XIII. The office of high or chief constable was established in England by Edward 1. (stat. Winch, 13 Edw. I.). He appointed two in every hundred to view the armour of every person within the same, to present all such defaults before the justices; to present the defaults of tourns, of highways, and of such as lodged strangers in uplandish towns for whom they would not answer. Their powers were, by several acts of parliament, enlarged, and they are now conservators of the public peace in their hundreds, as the petty constables are in parishes; and they serve precepts or warrants on certain occasions, and return the list of jurors. They are appointed at the courts leet of the franchise or hundred over which they preside, or, in default of that, by the justices at their special sessions. Petty constables, or parish constables, seem to have been first appointed about the beginning of the reign of Edward III., to alleviate the burthen of the chief constable. They are now appointed by the justices under 5 & 6 Vict. c. 109; and by that act it is declared that the leet shall appoint no constable except for the performance of duties unconnected with the public peace. Their principal duty is the preservation of the peace and the service of the summonses and the execution of the warrants of the justices of the peace, to them directed, relative to the apprehension and commitment of offenders. Special constables are persons appointed on particular occasions by the magistrates, who have

# Constitution

the grand ducky of Baden, Germany, between 1414 and 1418. It was summoned at the request of the emperor Signature of the second of the great schem in the Church arising from the contest between John XXIII., Gregory XII., and Benedict XIII. for the papal chair: and also to prevent the spread of the doctrines of John Huss. There were assembled, besides the emperor and Pope John XXIII., twenty-six princes, one himdred and forty counts, twenty cardinals, seven patriarchs, twenty archbishops, ninety-one bishops, six hundred prelates and doctors, and about 4,000 priests This council deposed the three rival popes, and elected. Martin V. as head of the Church, and tried and condemned to the stake both John Huss and Jerome of

CONSTANTINOPOLITAN HISTORY. (See BYZANTINE

EMPIRE.)

CONSTELLATION, kon-stel-lai'-shun (Lat. con, to-gether; stella, a stur), in Astron, the name given to large clusters of stars which occupy a considerable space in the field of the heavens, and are distinguished by names and grouped within fanciful outlines of men, animals, and things, principally derived from persons and incidents mentioned in the mythology of the Greeks and mondents mentioned in the mythology of the treess, and Romans. Aratus and Ptolemy among the ancients, and Bayer, Helvetins, and Lacaille, in more modern times, are the principal astronomers who have grouped the stars into constellations. Tycho Brahe, Lemonnier, Bezobut, and Halley, have added five more, which are recognized. Many more have been named by these and other astronomers, which are not admitted into the list of acknowledged constellations. Bayer commenced the notation of the stars in the various constellations by the Greek alphabet, marking the brightest star by the first letter, and so on; and when there were more stars than Greek letters, he denoted the rest by small italics. The stars were numbered in each constellation by Flamsteed, in the order of their right ascension, and this is the plan smally adopted in the catalogues of Bradley, Lacaille, and others. There are forty-eight constellations given by Aratus and Ptolemy, which are depicted on the by Aratis and Trotein, which are depleted on the celestial globe and in star maps; but as many more have been added since the time of Ptolemy, some of which are rejected; so that the acknowledged number is about ninety. The principal constellations are noticed under their respective titles.

Constitution, kon-stip-at-shun (Lat. constitution constitution, 1 crowd together), in Med., is a torpitude or sluggishness of the howels, occasioned by an excessive action of the absorbents of the bowels, or defective secretion of the juices of the intestines, by which the frees become hardened, or by an impaired peristaltic action of the intestines. (See Digestion.) It arises most frequently from a deficiency or vitiated secretion of the bile, which is the natural stimulus of the bowels. Sedentary habits predispose to constipa-tion, as does also the use of certain kinds of food. When severe and obstinate, it gives rise to inflammation of the bowels, and may soon prove fatal. The treatment consists in moving the bowels by means of purgatives, and then restoring the natural state of the system by means of active exercise in the open air, seabathing and the use of food of a laxative nature; as

brown bread, green vegetables, &c.
CONSTITUENT ASSEMBLY, in French Hist. (See

ASSEMBLY, NATIONAL.)

CONSTITUTION (Lat. constitutio, from con, and statue, I set, fix, or appoint), in a general sense is an ordinance, regulation, or law, made by authority of a superior, either civil or ecclesiastical. The decrees and decisions of the Roman emperors were called constitutions, and in the Roman church this name is

given to a decree of the pope in matters of doctrine.

Constitution in a political sense is the established warrants of the justices of the peace, to them directed, relative to the apprehension and commitment of offenders. Special constables are persons appointed on particular occasions by the magistrates, who have power to appoint and swear in as many householders or others as they may think fit, who have no legal exemption from the office of constable. County and district constables are appointed by the justices under the 2 & 3 Vict. c. 93, and 3 & 4 Vict. E. 89. (See Policia.)

Constance, Council of, kon-sidins, a celebrated ecclesiastical council held at the city of that name in 553. been divided into three kinds:—(1) those established by the sovereign power; (2) those springing out of rights enjoyed by the people, or certain classes of them, and which form conditions in the contract between the sovereign and the people; and (3) those founded on compact between different sovereign powers. The first class may again be divided into those established by a free sovereign people for their own regulation, and those that are granted by monarchs to their subjects. In regard to political principles, constitutions are—(1) democratic, where the sovereign power is vested in the body of the people; sovereign power is vested in the body of the people; (2) aristecratic, when the government is chiefly or entirely in the bands of certain privileged classes; (3) monarchical, when in the hands of one person; and (4) of a mixed character, as in Britain, where the sovereign power is distributed over the king, lords, and commons. Constitution always implies a sovereign power, whether that be vested in one or many, in one supreme ruler, or in all the male population above a certain age.

CONSTITUTION, kon-stit-tu'-shun in Med., is used to denote the general condition of the body, as evinced by the peculiarities in the performance of its evanced by the peculiar predisposition to certain diseases, the liability of particular organs to disease, varieties in digestion, in muscular power and motion, in aleep, in the appetites, &c. Some marked peculiarities of constitution are observed to be accompanied with certain external characters, such as a particular colour and texture of the skin and huir, and also with a peculiarity of form and disposition of mind. These have been observed from the earliest times, and have been divided into classes. (See TEMPERAMENT.)

CONSTITUTIONS AND CANONS. (See CANONS OF THE CHURCH OF ENGLAND.)

CONSTITUTIONS APOSTOLICAL. (See APOSTOLICAL CONSTITUTIONS.)

CONSTITUTIONS OF CLARENDON. (See CLARENDON,

THE CONSTITUTIONS OF.)
CONSUBSTANTIAL, kon-sub-stün'-shül (Lat. con, and substantia, substance), a term used in Theol. to denote something co-essential, or of the same substance, with sometiming co-essential, or of the same substance, with another. It is generally employed to designate the belief that the Son of God is of the same essence with the Father, and was first adopted by the council of Nice to express the orthodox doctrine, and to serve as a barrier against the errors and subtilities of the Arians, who denied this doctrine. The Greek term is homoousios.

Consubstantiation, or Impanation, kon-sub-stan-she-ai-shun, im-pan-ai-shun, is employed to designate the doctrine of the Lutheran church regarding the presence of Christ in the Eucharist, as opposed to trensubstantiation, the docrine of the Roman church. While the Romanists bold that the bread and wine of the Sacrament are changed into the body and blood of our Lord, Luther and his followers attempted to solve the mystery by maintaining that, through the conse-cration of the elements, the real body and blood of our Lord became united therewith, and were thus par-taken of by the recipients. This doctrine was first introduced into the Church about the end of the 13th century, by John, surnamed Purgens Asinus, a doctor of Paris, and is still held by Lutherans.

Consult, kon'-rul, in Pol., is a public officer appointed by a government to reside in some foreign country, in order to facilitate and protect the commercial relations between his own country and that to which he has been sent. This class of officers seems which he has been sent. This class of officers seems to have been created by the Italian states about the 12th century. Taking advantage of the crusades, they procured permission from certain Asiatic princes to send persons into their territories as protectors of their merchants going to these parts. Their example was gradually followed by other European nations, and by the 16th century the system was generally established over Europe. The right of sending conand by the 16th century the system was generally established over Europe. The right of sending consumed productive consumption. Commodities are consumed productively when the advantage or benefit, widely in different states. In general, the duty of a consumed unproductively when such advantage or consumed productively when the advantage or benefit, widely in different states. In general, the duty of a consumed unproductively when such advantage or consumed in the advantage or consumed unproductively when the advantage or consumed productively when the advantage or consumed unproductively when the advantage or consumed unproductively when the advantage or benefit is less than their value.

Consumed productive consumption. Commodities are consumed productively when the advantage or benefit is less than their value; and they are consumed unproductively when the advantage or benefit, and they are consumed unproductively when the advantage or benefit is less than their value; and they are consumed unproductively when the advantage or consumed unproductively when the advantage or benefit, and they are consumed unproductively when the advantage or consumed productively when the advantage or benefit, and they are consumed productively when the advantage or benefit, and they are consumed productively when the advantage or consumed productively when the advantage or benefit, and they are consumed unproductively when the advantage or consumed unproductively when the advantage or consumed unproductively when the advantage or benefit is less than their value; and they are consumed unproductively when the advantage or consumed unproductively when the advantag

other subjects; to prevent their infringement of the laws; to reconcile their differences, uphold their intelaws; to reconcile their differences, uphold their interests; and generally to ronder the condition of the subjects of the country employing him within the limits of his consulship as comfortable, and their transactions as profitable and secure, as possible. Consuls occasionally partake of a certain kind of diplomatic character; and in Turkey, according to an ancient treaty and certain by-laws of the Levant Company, British consuls enjoy extensive judicial powers. A British consulis expected to be master of the language of the country in which he resides, and to have a of the country in which he resides, and to have a knowledge of its laws and regulations, particularly such as relate to trade; to procure and send home statistical returns connected with commerce, and the prices of produce and provisions; and to report any in-lections disorders that may be within his district. Con-suls are sometimes natives of the countries in which they reside, but more frequently of the countries which they represent. All British consuls holding a royal commission are subjects of Great Britain, but many of the vice-consuls are not so. The emoluments of British consuls were formerly derived chiefly from fees, which depended upon the tonnage, number, value of cargoes, &c., of the British vessels entering and leaving the limits of their consulship; but now their fees are very inconsiderable, arising from notarial acts, certificates &c.; and, in addition, they have in many cases fixed salaries from the crown. In some cases they are allowed to engage in trade; in others they are interdicted from it. In most cases the salary is small, but in some it is as high as £1,600 or £1,800 a year. There are English consuls or vice-consuls at all the chief ports with which the nation has commercial relations. In with which the nation has commercial relations. In some countries, where there is no superior diplomatic agent, a consul-general is appointed, who is, sometimes, accredited as a political agent, with the rank of chargé d'afaires, and is resident at the scat of government. The total number of British consuls-general, consuls, and vice-consuls is about five hundred, of whom about one-half receive salaries. The government estimate of salaries to these for 1860-61 was £129,229.

CONSUL, the highest ordinary magistrate in the

ancient Roman republic. Consumption, in Med.

CONSUMPTION, in Med. (See PHTHISIS.)
CONSUMPTION, kon-sumpl-shun (Lat. consumptio), in Pol. Econ., is employed as opposed to production. It does not mean the consumption or annihilation of matter, that being as impossible as its creation, "but the consumption or annihilation of the qualities which render commodities useful and desirable. To consume the products of sit or industry, is to deprive them of the utility, and, consequently, of the value communi-cated to them by labour." "We produce commodities only that they may be used or consumed. Consump-tion is the end and object of human industry; pro-duction is merely a means to attain that end."—(J. R. McCulloch.) In this sense, then, consumption is synonymous with use, and is the end or object of production. "It would be an improvement," says Professor Senior, "in the language of political economy, if the expression 'to use' could be substituted for that of 'to consume.'" "That almost all that is produced is destroyed, is true; but we cannot admit that it is produced for the purpose of being destroyed. It is produced for the purpose of being made use of. Its destruction is an incident of its use not only not intended, but, as fur as possible, avoided." In every beatthy condition of secient there is always a natural intended, but, as far as possible, avoided." In every healthy condition of society there is always a natural relationship maintained between production and consumption. The greater the consumption, the greater the stimulus given to production. There will always be an excess of production over consumption wherever the course of industry is not impeded by bad laws. Political economists distinguish between productive and variety decise consumption. Commodities

# Continent

a healthy body by actual contact with the sick, or with the palpable matter from their bodies, and infection to be applied where disease is communicated through the medium of the atmosphere, or by means of other intermediate substances, called fomites. This distinction, however, is frequently lost sight of, and the term contagion applied to all cases in which the discase is conveyed to the person of the recipient by par-ticles of matter proceeding from the person of the sick, whether these particles are in a solid or a gaseous form, whether they are imparted by direct contact of the two bodies, or by being wafted through the air, or carried upon articles of clothing. There are two kinds of contagious diseases: (1) Those that can only be comminguised by direct contact as each problem and the direct contact as each problem. municated by direct contact, as itch, syphiliz; and (2) those which are capable of being produced either by direct contact or without it, as small-pox, typhus fever, &c. Some contagious diseases seem to effect some radical charge upon the contact. some radical change upon the system, so that it is not again liable to attack from the same disease, as smallpox; and some diseases, that do not generally manifest any contagious disposition, do occasionally, under unfavourable circumstances, assume a malignant and contagious form. The term contagion is also applied to the poisonous matter by means of which the disease is communicated. In this latter sense, it is a morbifle matter sui generis, which, on entering the blood, produces a definite train of morbid phenomena, and communicates to the blood the property of generating a similar poison capable of producing precisely the same disease,

CONTINENT, kon'-tin-ent (Lat. con, and tenens, holding), a large tract or division of land not separated by the sea from other lands, or a connected tract of land of great extent, whether an island or not. The surface of the earth is divided into five continents, which are generally recognized; namely, Europe, Asia, Africa, America, and Australia.

CONTINENTAL SYSTEM, kon-te-nen'-tal, was a plan devised by Napoleon to exclude Britain from all intercourse with the continent of Europe, in order to comcourse with the continent of Europe, in order to compel her to acknowledge the maritime law established at the peace of Utrecht. This system began with the famous decree of Berlin (Nov.21,1806), which declared the British islands to be in a state of blockade; all commerce, intercourse, and correspondence, at an end; every Briton found in France, or a country occupied by French troops, a prisoner of war; all property belonging to Britons fair prize, and all trade in British goods entirely prohibited. Britain immediately directed perspeals are the decree and by an on Drusa goods entirely prohibited. Britain immediately directed reprisals against this decree, and by an order in council of 7th January, 1807, she prohibited all neutral vessels from cailing to any port belonging to France or her allies, or to one of any nation so much under her control that British vessels could not have introduced with it. have intercourse with it. Every neutral vessel which should violate this order was to be confiscated with her cargo. A second decree of 11th November, 1807, was still more severe against neutral commerce. this, all harbours and places of France, and her allies in Europe and the colonies, as likewise every country with which Britain was at war, and from which the British fing was excluded, were subject to the same restrictions as if they were closely blockaded; all commerce in the manufactures and productions of such countries was prohibited, and vessels engaged in such commerce were to be confiscated; as also all those reseels whose certificates showed that they were built in the enemy's country. Another order in council declared the sale of vessels to neutrals by the enemy unlawful, and the intended transfer of property void. These orders were followed by reprisals on the French side. By a decree of Milan, of 17th December, 1807, atrengthened by a decree of the Tuileries of 11th January, 1808, every vessel, of whatever flag, which had been searched by a British vessel, and cousented to be sent to Britain, or had paid any duty whatever to Britain, was to be declared denationalized, and to have become British property, and as such a good prize. In order more effectually to annihilate British prize. In order more enectually to annihilate British commerce, the turiff of Trianon respecting colonial goods was proclaimed 3rdsAugust, 1819, which was extended by a decree of 12th September, and on the 18th October was followed by the decree of Fontaine-bleau, which directed the burning of all British goods.

#### Contract

These decrees were to be carried out, with more or fewer modifications, in all countries connected with France. The consequence was, that the price of colouisl and foreign goods rose enormously on the conlomial and foreign goods rose enormously on the con-tinent; a regular smuggling trade was carried on at different points; numerous substitutes for colonial goods, particularly coffee and sugar, were invented; and a variety of manufactures grew up on the con-tinent which were the germs of very extensive and flourishing branches of industry. On the breaking up of Napoleon's power, the so-called continental system fell to the ground fell to the ground.

CONTINGENT, kon-tin'-jent (Lat. con, and tange, I touch), in Pol., is the name given to the quota of troops to be furnished by each member of a number of

states composing a confederation.

CONTINGENT LEGACY. (See LEGACY.)

CONTINGENT REMAINDER. (See REMAINDER.)
CONTINGENT USE. (See USE.)
CONTOUR, kon-toor' (Fr. contour, from Lat. conforquere, to bend or twist), a name which is sometimes given to the outline by which any figure or form is defined or expressed. It is also applied to the coasi-line of a country and the undulations of its auxiliary referring chiefly in the latter case to the outline of kill and dale obtained by making a section of it in any direction. We often speak of the contour of a figure, and associate it with an outline consisting of beauti fully rounded curves rather than with one which is full

of abrupt turns and angular projections.

Contraband, kon triband (Ital contrabands; Lat. contra, against, and bannum, proclamation), in Comi, is applied to all goods or wares exported from or imported into, any country against the laws of said

country.

CONTRABAND OF WAR, is a designation applied to certain commodities useful in war, which, by the law of nations, neutrals are prohibited from carrying to beligerent states. According to Vattel, "such are arms, ammunition, tabler for shipbuilding, every kind of naval stores, horses, and even provisions in certain inventions. junctures, when we are in hopes of reducing the enemy by famine." There is great difference of opinion by famine." There is great difference of opinion among authorities as to what are and what are not contraband of war, and the usage among nations has been equally fluctuating. Grotius divides commodities into three classes: (1) Those which are useful only for the purposes of war; (2) those which are not so; and (3) those which are susceptible of indiscriminate use both in war and peace. The first he, with all other authorities on the subject records as attickly contraauthorities on the subject, regards as strictly contra-band of war, and prohibited from being carried by neutrals to the enemy; the second he permits to be so carried; and the third, such as money, provisions, ships, and naval stores, he sometimes prohibits and at other times permits, according to the existing circumstances of the war. Of the same nature with contraband goods is the carrying of military persons or dis-patches in the service of the enemy. The dispatches of an ambassador or other public minister of the enemy resident in a neutral country are excepted. In general, where the ship and cargo do not belong to the same person, the contraband articles only are confiscated, and the carrier-master is refused his freight to which he is entitled upon innocent articles which are condemned as enemy's property. Under the fraudulent circumstances of lalse papers and false destination, the ship as well as the cargo is liable to confiscation. Where the ship and the contraband articles belong to the same person, they are involved in the same

CONTRACT, kon'-trakt (Lat. con, traho, I draw). The subject of contract (Lat. con, train, 1 draw).—
The subject of contracts is partly treated under the
head of AGREEMENT. In addition to what is there
stated, it may be remarked that contracts are express
or implied, the terms of the former being openly,
uttered and avowed at the time of the making; the latter rest on a mere construction of law, and in general it will be implied that a men actually promises to fulfil that which he ought to fulfil. (See BAILMENT.)
Where there is an express promise, the law does not raise an implied one in reference to the same matter,for expressum facit cessare tacitum; and where there is a contract by deed, no express parole promise to the same effect and upon the same subject can coexist with

### Contraction

it, for the contract by specialty merges or extinguishes that by parole. A parole contract may be either written or verbal. A contract may be either executed, as if A. agrees to change horses with B., and they do it immediately, in which case the possession and the right are classety, in which case the possession and the right are transferred together; or it may be executory, as if they agree to exchange next week; here the right only vests, and their reciprocal property in each other's horse is not in possession, but in action; for a contract executed (which, when it relates to an exchange or sale of goods, differs in nothing from an assignment) conveys a chose in possession; a contract executory conveys only a chose in action. (See Chose in Action.) A promise by parole only is not binding in law, unless made upon a consideration, or some compensation or quid pro quo, to be reciprocally afforded by the promisee. As a general rule, the adequacy of the considera-tion is a question that the law will not entertain, provided a consideration of some value shall appear to ave existed. (As to a contract by deed, see DERD.) There are some rules applying indifferently to all kinds of contracts. They relate to the capacity of persons to contract, and to the construction and performance of contracts when made. Those which relate to capacity principally concern the condition of insanity, drunkenness, infamy, coverture, and duress. (See the references under the article Caracity, Legal.) In addition to the matter explained under the heads of subjects so referred to, it may be stated that a person drunk, to the extent of complete intoxication, so as to be no longer under the guidance of reason, is absolutely incapable, while that condition lasts, of entering into a valid contract. The rules which govern the construction or interpretation of a contract when made will be mentioned when we consider the article DEED, as the same laws of construction apply in general both to sealed and unsealed agreements. The performance of sealed and unsealed agreements. The performance of a contract cannot be enforced if the contract be founded upon an immoral or illegal consideration, or be obtained by fraud, or, if good at the time of making it, the per-formance becomes illegal by a subsequent alteration of the law, or if the promisee on his part has failed to perform the consideration. But, on the other hand, no excuse is in general afforded by the circumstance that what a man absolutely engaged to do has since become impossible, for it was his own fault to make an unconditional contract. Yet, if the performance be hindered by the opposite party, the case, of course, is different, and the party making the engagement

excused. CONTRACTION, kon-trük-'shun, in Gram., is the short-ening of a word by the omission of a letter or syllable. The Greek language abounds with contractions, which have been adopted chiefly to avoid a harshness in the pronunciation arising from the concurrence of two rowels in two successive syllables or words. Hence two or more simple vowels coming together are usually contracted into a diphthong. This is said to be proper when the vowels are contracted without change into a diphthong; improper, when, in the contraction, a vowel or diphthong of a different sound is substituted. Elision takes place when two vowels at the end of one and at the beginning of another word come together, and the final wowel of the first word is rejected, its place being marked by an apostrophe placed over the consonant which is left. This takes place chiefly with the poets. Crasis is that kind of contraction in which two words coalesce into one, and are accented as one, with-out any elision. In synizesis two vowels are contracted into one sound-not in writing, but in pronunciation. In the Middle Ages, before the introduction of print ing, numerous contractions were resorted to for the purpose of abbreviating the labour of transcription. In many of the arts and sciences contractions are still common. (See ABBRYIATIONS.)

Contradiction: Propositions, kon-tra-dik'-tor-c
[Let. contradictio], in Log., are the opposities of each
other, the one being a mere and naked denial of the
other. To be truly contradictory, they must have the
same terms, and differ both in quantity and quality,—
the one denying and the other affirming the same
thing of the same subject considered in the same cirsummissiones.

CONTRALTO, kon-trall-to (Ital.), in Mus., is a term em-

### Convention

that part in the score whose range of tones lies between that of the tenor and that of the soprano or trable, also called the alto or counter-tenor.

CONFRIET PROPOSITIONS, kon-tra-re-[Lat. contrarius], in Log., are universal propositions, one of which affirms and the other denies the same predicate of the same subject. They differ in quality, but not in quantity, and, therefore, are distinguished from contradictory propositions, which differ both in quantity and quality.

Contrition, kontrish'un (Lat., from contero, I break or bruise), in Theol., is deep sorrow for sin, arising from the thought of having offended an infinitely holy and benevolent God. It is usually understood to mean genuine repentance, and to be accompanied with a detestation of sin and of oneself on account of it

CONTROLLER, or COMPTROLLER, kon-kroal'-er (Norm.), is an officer appointed to control, over-see, or verify public accounts; as the comptroller of the royal household, whose duty it is to examine and check the expenses of the household. He is usually a member of the privy council, and a political adherent of the government in power. The comptroller-general of the exchequer has the control and record of the receipts and payments of the public revenue of the United Kingdom, and the preparation and issue of exchequer bills. He is incapacitated from holding any other office under the crown, is appointed by letters patent, and holds his

office during good behaviour.

CONUNDRUM, ken-un'drum, a sort of riddle, in which
some quaint or odd resemblance is proposed for discovery between things perfectly unlike; as, for instance,
Why is a whisper like a forged bank-note?—Because
it is uttered but not not allowed (aloud).

CONVENT, kon'-cent (Lat. conventus, from con and vento, I come), is applied both to a community of religious persons, whether monks or nuns, and to the abbey, monastery, or nunnery in which they reside. (See MONASTERY NEWS.)

abbey, monsstery, or numery in which they reside. (See Monasterx, Nuns. Convent, denoting properly a cabel, or secret assembly, of a part of the monks of a convent to form a party in the election of an abbot. It is said by some to have been first applied in England to the schools of Wickleiffe, and has since been used by way of reproach for those religious assemblies which dissent from the established church. In 1664, what is called the Conventicle Act was passed, decreeing that if any person or persons above sixteen years of age were present at any meeting for worship different from the Church of England, where there should be five persons more than the household, they should, for the first offence, suffer three months imprisonment, or pay £5; for the second the punishment was to be doubled; and for the third they were to be banished to America, or pay £100; and if they returned, to suffer death. This act having expired, another was passed in 1669, according to which a fine of 5s, was to be inflicted for the first offence, and 10s, or the second; and any one preaching, or suffering a religious meeting to be held in his house, incurred a penalty of £20. By 1 Will, & Mary, c. 18, Protestant dissenters were freed from these penalties; but it was not till 1812 that the Conventicle Act was repealed by 52 Geo. III. c. 112.

Convention kon-cent-shun (Lat.), denotes properly the act of coming together, a meeting or assembly of several individuals. It is more particularly applied to a formal meeting, or an assembly of delegates or representatives for the transaction of important business, civil or ecclesiastical. In English Hist, it is the name given to an extraordinary assembly of parliament, or of the states of the realm, held without the king's writ. Of this kind was the parliament which restored Charles II., and that which conferred the crown upon William, prince of Orange. In the latter case, William, on the abdication of James II., invited the lords spiritual and temporal, to the number of shout ninety, all who had sat in parliament under Charles II., and the mayor, aldermen, and fifty common councilmen of the city of London, to meet and deliberate upon the state of the country. They recommended him to summon a convention of the states of the realm; and accordingly circular letters were dispatched to the several counties, cities, boroughs, and universities, for the election of members. The convention met on the 22nd June,

55G

# Convention of Royal Burghs

1639, and, after long debate, passed the Act of Settlement, which declared the throne vacant, and conferred the crown, with its prerogatives more exactly limited and defined than formerly, on William and his princess jointly. A similar convention met at Edinburgh in March, 1689, and, after declaring that James had forfeited all title to the throne, made a tender of their Regione to the prince and princess of Orange.—In French Hist, the term is applied to that assembly which met after the Legislative Assembly had promoned the suspension of the royal functions in September 1988. nounced the suspension of the royal functions in September, 1792, and proclaimed the republic. This body dissolved itself on the establishment of the Directory, in October, 1796.—In the United States, meetings of the people of separate states by specially chosen representatives, to rovise and amend the state constitutions have been named conventions. tions, have been named conventions.

CONVENTION OF ROYAL BURGUS. ROYAL.)

CONVERSATION, kon-ver-sai'-shun (Lat. conversatio from on, and oerfor, I turn), denotes familiar discourse or easy talk between two or more persons, and is opposed to a formal conference. The pleasure and advantages to be derived from conversation are very manifest. There is much in it to lead the superficial observer to view it as a natural gift; and we find indi-viduals, and even nations, that have peculiar talents for it; but still it is an art, and may be learned like every other art, and from its value and importance it is entitled to much more attention than is usually bestowed upon it, at least in this country. Let a man have read, thought, studied as much as he may, rarely will be reach his possible advantage as a ready man, unless he has exercised his powers much in conversu-tion. De Quincey goes farther, and not only regards conversation as giving greater facilities to a person in expounding or diffusing the truth, but as giving a new insight into the truth itself. "A feeling dawned on me," he says, after narrating his carly dislike of conversation, "of a secret magic lurking in the peculiar life, velocities, and contagious ardour of conversation quite separate from any which belonged to books; arming a man with new forces, and not merely with a new dexterity in wielding the old ones. I felt, and in this I could not be mistaken, as too certainly it was a fact of my own experience, that in the electric kindling of life between two minds, and far less from the kindling natural to conflict (though that also is something), than from the kindling through sympathy with the object discussed in its momentary coruscation of shifting phases, there sometimes arise glimpses and sby revelations of affinity, suggestion, relation, analogy, that could not have been approached through any avenues of methodical study." But in relation to the majority of men, conversation is far less valuable as an organ of intellectual culture than of social enjoyment. For one man interested in conversation as a means of advancing his studies, there are fifty men whose interest in conversation points exclusively to convivial pleasure. This, as being a more extensive function of conversation, is so far the more dignified function; whilst, on the other hand, such a purpose as direct mental improvement seems, by its superior gravity, to challenge the higher rank."—(Essay on Conversion) Conversation.) The ancient philosophers were masters of the art of conversation, and adopted this mode of communicating instruction to their disciples. In modern times the French are distinguished, among all anomer lines the French are distinguished, among all other nations, for sparkling, fluent, suimated, and delightful conversation. The Encyclopédie Moderne says, not without some truth,—"Les Allemands ne causent pas, ils argumentent; la conversation des Italiens est une pantomime mélée d'exclamations; chez les Anglais, ce qu'on nomme conversation est un silence syncopé par des monosyllabes et interrompu de quart d'heure en quart d'heure par le bruit de l'eau qui s'échappe de l'urne à thé; chez les Français la conversation est un art qui a ses principes, ses règles, ses préceptes, et sa methode." Housseau justly remarks that the tone of good conversation is neither dull nor frivolous. It is iluent and natural; sensible, without being pedantic; cheerful, without being boisterous; elegant, without being affected; polite, without being insipid; and jocose, without being equivocal. It deals not in dissertations or epigrams; conforms to the de-

### Convict

mands of good taste, without being bound by rule; unites wit and reason, satire and compliment, withous departing from the rules of a pure morality, and allows all to speak on subjects which they understand. Each all to speak on sunjects which they understand, expresses his opinion, and supports it in as few words as possible; and no one attacks that of another with warmth, or upholds his own with obstinacy. All impart information, and all are entertained. In this art, as in most others, it is more easy to indistant things are to be avoided than to main the control of the standard what things are to be avoided than to main the sunjects when the same to be avoided than to main the same than the same to be avoided than to main the same than the same that the same than the same tha cate what things are to be avoided than to point out precisely what ought to be done. The object of conversation is to afford entertainment or agreeable information; and one of its first rules is to allow everybody to contribute his share, while every one at the same time ought to exert himself for the gratification of the company. Egotism, or any display of self-conceit, is the very bane of conversation, and carefully to be avoided, as is also tediousness in narration. Adapt yourself to your company, and your conversation to your talents and information. Good sense and good feeling should guide in the selection of topics for conversation, and prevent the introduction of subjects that may not be agreeable to the company. The great art of conversation is to keep it constantly flowing, and to seize upon points which can turn it into new cleaneds. "La conversation n'est point une course vers un but, une attaque régulière sur un point, c'est une promenade au hasard dans un champ spacieux, où l'on s'approche, on s'évite, on se froisse quelquefois sans se heurter jamais."—(Encyclopédie Moderns.) It is much to be regretted that an art which occupies such an important place among the accomplishments of social life is yet so much neglected as it is among us. It is one of the most important means that can be employed in the intellectual training of children, and yet it is entirely neglected in the schools. This is one of the errors that exist in our present artificial system of education, when children are taught subjects for which they will have little or no use in after life, to the entire neglect of such as will daily concern them.

thre neglect of such as will daily concern them. Conversations LEXIKON. (See Encyclor EDIAS.) CONVERSION, kon-eer-shun (Lat. concersio), in Log., conversion from another, by is the forming of one proposition from another, by interchanging the subject and predicate, thus: the converse proposition of "Every A is B," is, "Every B is A." There are three kinds of conversion,—simple, limited, and by contra-position. In simple conversion, both quantity and quality are retained, as in the example just given. Universal regative and particular affirmative propositions may be simply converted. affirmative propositions may be simply converted. It requires, however, that the extremes be of equal extent, — that is, either both distributed or neither distributed; as, "Every equilateral triangle is equiangular;" "Some poor persons are liberal." In limited conversion the quantity of universal affirmatives and universal negatives is changed; as, "All oaks are trees," "Some trees are oaks;" "Nothing that is morally right can be politically wrong," "Nothing politically wrong can be morally right." Conversionable proposition is applicable to universal affirmatives by juxtaposition is applicable to universal affirmatives and particular negatives, and consists in the combining with each of the transposed extremes the pair no not; as, "Whosoever is of God doeth righteensness," Whosoever doeth not righteensness is not of God."

Conversion, in Law, is where a man has found, or becomes possessed of another's goods, and refuses to deliver them on demand; in which case he is said to have converted them to his own use. And an action of trover will lie to recover the goods, or the value thereof.

CONVERT, kon'-nert (Lat.), is one who changes his religion, and is specially applied to such as abandon any other faith and adopt that of Christianity. It is opposed to apostate, applied to one who has forsaken the Christian religion for some other.

CONVEX. (See CONCAVE.)

CONVEX. (See CONCAVE.)

CONVEYANCE, kon-vait-ins (Lat. con, and veho, I carry), in Law, is a writing, sealed and delivered, whereby the property in lands and tenements is constituted by the property in lands and tenements is constituted by the control of the property in lands and tenements is constituted by the control of the property in lands and tenements is constituted by the control of the property in lands and tenements is constituted by the control of the contr veyed from one person to another. Where the property in goods or in a term of years, or other estate less than freehold, is passed by deed, the instrument of transfer is called an assignment. (See Assign-

CONVICT, kon'-vikt (Lat.) denotes generally one

# Conviction

convicted of a criminal charge, particularly of a cerious nature. In a special sense, it is applied to such as have been sentenced to transportation or penal servitude. (See PRIVAL STRUIDS, PRIVADO STRUIDS, CONVICTION, Reservit Shum (Lat.), is a record of the

summary proceedings upon any penal statute before one or more justices of the peace, or other persons duly authorized in a case where the offender has been

convicted and sentenced.

CONVOCATION, kon-vo-kai'-shun (Lat. con, and roco Really, an assembly of the clergy of the Church of England, by their representatives, for the purpose of consulting on ecclesiastical matters. They were originally ecclesiastical councils of the archbishops, summoned for the consideration of spiritual matters; but manuel for the consideration of spiritual matters; but they afterwards came to be endowed with certain par-liamentary privileges. Convocations were first as-sembled in England, under the king's authority, by Edward I., who summoned them by writ, directed to the two archbishops, for the purpose of obtaining subsidies from the clerical body. Subsequently, con-vious tions continued to be held without royal authority that the passing of 25 Henry VIII., which declares that meither archbishop can summon a convocation withneither archbishop can summon a convocation without the king's command, nor continue it after it is com-manded to cease. When assembled, they cannot confor to constitute any canons without license from the king, nor can they execute any of their canons without royal assent. They cannot execute any after royal assent, but within the four following limitations:—(1) That they be not against the prerogative of the king; (2) nor against the common law; (3) nor against any statute law; (4) nor against any custom of the realm. In 1661, convocation granted a subsidy to Charles II., which was the last tax of the kind paid by the English clergy; for by an arrangement made between Archbishop Sheldon and Lord Chancellor Clarendon in 1664, the convocation of the clergy gave up the privilege of taxing themselves to the House of Commons, in consideration of their being allowed to vote at the election of members of that house. Since that time, convocation exists in little more than name and form. On the meeting of every new parliament, the arch-bishops of Canterbury and York, in obedience to a writ issued from the crown, convoke the bishops, and the bishops the clergy of their respective dioceses. After the transaction of a few formal matters, the meeting is generally prorogned. Convocation, like parliament, consists of two distinct houses,—the one realight the upper house, where the archibishop and bishops sit, and the other the lower house, where the rest of the clergy are represented by their deputies. In the convocation of York, however, on the rare occasions on which it meets, the business is generally conducted in one assembly. Some attempts have recently been made to rescue convocation from its present lifeless state, but hitherto with very little effect.

CONVOLVULACEE, kon-nol-nu-lai-see (from Lat. convolvo, I roll or bind together), in Bot., the Convolvolus or Bindweed fam., a nut. ord. of dicotyledumous plants in the sub-class Carolliflora. Harts or shrubs generally twining or trailing, and milky. leaves are alternate and exstipulate. The calyx has the deep divisions; is much imbricated, persistent.
The corolla is 5-partite or 5-plaited, regular, deciduous, and has no scales in its tube; estivation plaited. There are five stamons alternate with the lobes of the corolla. The overy is 2-, 3-, or 4-celled, or its carpels are more or less distinct. The fruit is capsular. In this order there are 47 known genera, with about 665 species, which are chiefly found in the plains and valleys of hot and tropiesi regions. A few flourish in temperate climates, but none in the coldest latitudes. They are remark-able for the presence of an acrid milky purgative juice in their roots. Jalap and scammony are products of this order.

CONVOLVULUS, kon-vol'-ou-lus, in Bot., the Bindweed, Ochronitions, kon-vol-val-lus, in Bot., the Bindweed, agen, of plants, the type of the nat. ord. Convoluntacea. It is characterized by a bell-shaped corolla, with five prominent plants and five shallow lobes. Three species are natives of Britain; namely C. arvensis, Sepium, and Soldansila. C. Scammonia, a native of Asia Minor, is a rainable medicinal plant, being the source of the purgative gum-resin called scammony. This is obtained from the fresh root, by cutting, the top obliquely of,

# Coolies

and allowing the milky juice which exudes to be est lected in shells or other vessels. The greater part of the scammony of English commerce is imported from

Smyrna. It is usually much adulterated.

Convoy, kon'-voi (Fr. convoi), in Mil, a train of waggons laden with provisions, accompanied by a detechment of troops to guard them from falling into the hands of the enemy .- In Mar., the name is given to some of her Majesty's ships that sail with a fle merchant-vessels in time of war, to protect them from the enemy's cruisers in their transit from one post to another. If any of the ships thus protected get can-tured, through neglect on the part of the master to obey signals, or from parting company with the comvoy, the policy of insurance effected on the vessel and cargo before starting becomes void.

CONVULSIONARIES, kon-vull-shun-d-res, the name given to a fanatical sect of Jansenists, who made their appearance in Paris about 1730. They used to accemble at the grave of a celebrated Jansenist named Francis of Paris, in the churchyard of St. Medardus, and there work themselves up into the greatest agitations or convulsions, preaching, prophesying, and prefessing to receive wonderful revelations. They threw themselves into the most violent contortions of body, rolled about on the ground, imitated birds and beasts, and when they had completely exhausted themselves, went off in a swoon. In 1732 the king caused the churchyard to be walled in and a watch set over it. and, the following year, he issued orders for them to be imprisoned; but even these steps did not entirely put a stop to their fanaticism.

CONVULSIONS, kon-vull-shans (Lat. conveile, I pull together), in Path., is a violent and involuntary contraction of the muscles of the human body, generally with corresponding relaxations, but sometimes with rigidity and tension. The fits vary much in extent and violence, sometimes attacking the whole body, at other times only particular parts; sometimes lasting only for a few minutes, at other times continuing for hours. the affected muscles are rigid and tense, and their contraction persistent or not quickly alternating with relaxation, the convulsion or spasm is said to be tonic; when contractions and relaxations rapidly alternate, it is called clonic; when slight contractions rapidly alternate with relaxations, it is called tremor. Sometimes the attack is sudden and without any warning; but generally it is preceded by certain premonitory signs, such as giddiness, dimness of vision, coldness of the extremities, tremblings, and a cold air creeping up the back or up a limb. During the fit the teeth guash and often pite the tongue, the mouth foams, the eyes roll wildly about, and the whole face is distorted. The muscular force exerted is sometimes so great as to overcome the strength of several attendants. Great languor commonly succeeds, attended frequently with headache and giddiness; but these generally pass quickly away. In partial convulsions the mind is quickly away. In partial convulsions the mine rarely affected; but when general, it is in nost cases lost during the fit. The causes of convulsions are many and varied, and their treatment must in each case depend very much upon the cause. In children the common cause is irritation of the bowels, arising from gross and indigestible foods, teething, or worms. These are to be treated by the administration of appropriate purgatives and the lancing of the gums. In puerperal convulsions bleeding and opiates are the usual remedies; and in cases where they arise from violent affections of the mind, the exciting causes must be studiously avoided. During the fit the patient should be immediately surrounded as much as possible by fresh cool air, his face, neck, and bosom freely exposed to it, and everything tight about the body loosened. For children a warm bath is strongly recommended. The after-treatment consists in the judicious use of tonics and nervous stimulants, with cold bathing, regular exercise in the open air, plain but nourishing diet, and attention to the state of the

COOLERS, or COULES, koo'-less, was originally the name of one of the most fierce and barbarous of the aboriginal tribes of Hindostan, which abounds chiefly in the province of Gujerat. From the circumstance of many of these being afterwards employed as labourers and porters in Bombay and other parts of India, the

558

# Cooperage

name came to be applied by Europeans to that class of persons generally in India. It is now also applied of persons generally in India. to emigrant labourers from India and China to America.

the West Indies, and other parts.

Ocorreign, or Coorreing, koop'-er-ig, koop'-er-ing [Ang.-Sax.], the mechanical art by which casks, tube, barrels, and all kinds of wooden vessels bound together with hoops, are made. It is a very ancient art, and its invention is ascribed by Pliny to the people who lived at the foot of the Alps. On account of the abundance of wood, the fabrication of casks was early introduced into France, and from that country it was imported into Britain. The occupation of the modern cooper is divided into several distinct branches. dry cooper makes casks for containing all kinds of goods not in a liquid state; such as sugar, flour, &c. The west or tight cooper makes vessels for holding liquids; and this branch is subdivided into large and small work, which are kept quite distinct. There are, also, white coopers, or those who make tubs, pails, churns, &c.; and there are coopers in general, who undertake every variety of work. The unright pieces which form the sides of a barrel or cask are called staves, and the shaping and planing of these is the most difficult and the most important part of a cooper's work. Each stave must form part of a double con-coid; it must be broader in the middle, and gradually become narrower, but not in straight lines, towards the two extremities. The outside of the staves, across the wood, is wrought into segments of a circle, and is made thickest in the middle, growing gradually thinner towards the ends. When the staves are dressed and towards the ends. When the states are dressed and arranged in a circular form, the cooper can make their odges cuincide perfectly together. In the shape of the staves, and in giving the proper curve, consists the principal part of the cooper sart. The best work is made of eak, of which five kinds are used; viz., Quebec, Virginia, Dantzie, Hambro, and Euglish. Small dry casks or kegs are chiefly made of Quebec onk. All wood employed ought to be thoroughly dried before being put together.

OPERATION, ko-op'-er-ai'-shun (Lat. con, and opus, a work), denotes literally a working together, and in Pol. Ec. is applied to certain societies formed among the industrial classes for some commercial purpose.
The prevailing belief that the labourer does not work for himself, but for the capitalist,-that the latter obtains all the profit of his labour, -has led to the natural conclusion, that if he could work for himself, if he could supply capital as well as labour, then the whole of the profits would be his own. This has led to the formation of societies among the working classes, where, by each contributing a small sum to the general fund, they have obtained capital for the purpose of embarking in some commercial undertaking, the profits on which being afterwards divided among them, or going to increase their capital and enlarge the sphere of their operations. Thus, instead of putting their savings into a bank, or investing it in other securities which yield only a small interest, as the capital is om ployed by others, who must have their profits out of it, they employ it for themselves, and thus obtain the whole of the profits. Co-operation differs from comaunism, socialism, or any other fanciful scheme of civil society. It is simply a joint-stock company, car-cying on some commercial enterprise. It usually rying on some commercial enterprise. It usually takes the form of a society for supplying its members and others with articles of daily consumption. The goods are purchased with the money of the society, and sold at the ordinary market rate, the profits being periodically divided among the members, or going to increase the capital. At Rochdale, Leeds, and other places, co-operative societies of working men have been set on foot, and carry on large flour-mills, cottonfactories, and other industrial establishments. Each factories, and other industrial establishments. Lacon operative member receives weekly wages, and periodically a share of the profits. "The form of association," says J. S. Mill, "which, if markind continue to improve, must be expected in the end to predominate, is not that which can exist between a capitalist as chief, and workpeople without a voice in the manage-ment, but the association of the labourers themselves on terms of equality, collectively owning the capital with which they carry on their operations, and working ander managers elected and removable by themselves.

# Copernican System

"There is a capacity of exertion and self-denial is to masses of mankind which is never known but on a rare occasions on which it is appealed to in the mas of some great idea or elevated sentiment." The ay or some great mes or envised semiment. The attem of co-operation is one of great benefit to it working classes, if properly carried out. It fosts provident habits, and encourages industry. Has individual is as much as ever dependent upon his executions, which are also more suitably rewarded. leads, also, to strict inquiry into the moral character of such as are desirous of admission into their society, By several recent statutes, all the provisions relating to friendly societies have been extended to such asso-ciations of working men "as have been formed for the mutual relief, maintenance, education, and endowment of the members, their husbands, wives, children, or kindred; and for procuring them food, lodging, clothing, and other necessaries, by exercising or carrying on in common their respective trades or handicratts. (See FRIENDLY SOCIETIES, SOCIETIES.)

Coor, koot .- The habits of this bird closely resemble those of the common Galling. They are found in various parts of Europe, Asia, and America, but abound in larger numbers in Holland than elsewhere. It is about sixteen inches in length; its upper parts are slaty black, and its under lead-colour. From the bill almost to the crown of the head there is a fleshy excrescence, destitute of feathers, and smooth and round. On this account it is sometimes called the bald-headed

COPAIBA. (See COPAIFERA.)

COPAIREA. (c. pai: fe-rā (from copaibs, the Brazilian name, and Lat. fero, I bear), in Bot., a gen. of plants belonging to the nat. ord. Leguminoses, sub-ord. Geneal-pinies. The species are natives of tropical America, and several yield the valuable oleo-resiu which is used in medicine under the name of balsum of copaids.
This is obtained by making incisions into the stems of the trees. Most of the copsiba of commerce is brought from the Brazils, a very little being imported from Guians and the West-Indian islands. The timber known as the purple-heart, or purple-wood of Guiana, is the produce of C. pubifora, and probably C. brac-teata also. It is largely employed for making musket ramrods and for ornamental purposes.

COPAL. (See HYMENÆA.) COPALCHE BARK. (See CROTON.)

COPARCHNARY, ko-par-se-na-re (Norm.), is an estate where lands of inheritance descend from the ancestor to two or more persons. It arises either by common law or by particular custom. By common law, as where a person seized in fee simple or in fee tail dies, and his next heirs are two or more females, his daughters, sisters, sunts, cousins, or their representatives. In this case they shall all inherit; and these co-heirs are then called coparceners, or, for brevity, parecess. Parceners by particular custom are where lands descend, as in gavelkind, to all the males in equal degree, as sons, brothers, uncles, &c.

COFE, koap (Sax. coppe), is a kind of cloak or vest-ment worn by the clergy of the Anglican church during divine service. It reaches from the neck nearly to the feet, and is open in front, except at the top, where it is united by a band or clasp. The rubries of Ed-ward VI. prescribe a cope or vestment for the priest administering the holy communion, and for the bishops when executing any public ministration in the church, for which a vestment may be substituted either by priest or bishop.

COPE, among Miners, is a custom of tribute due to the Crown, or lord of the soil, out of the lead-mines of Derbyshire.

Cornc, ko-pek', a Russian copper coin, equal to the hundredth part of a rouble, which is about 3s. 2d. aterling.

COPERNICAN SYSTEM, in Ast., is the term applied to that system of astronomy propounded by the cele-brated Polish astronomer Nicholas Copernicus, who was the first to affirm that the sun and stars are stationary; that the moon alone revolves about the earth; that the earth is a planet, whose orbit is between Venus and Mars; that the planets revolve about the sun; and that the apparent revolution of the leavens is caused by the rotation of the earth on its axis. (See Astro-NOMY, PTOLEMAIC STATEM.)

559

COPRENIUM, ko-per-nisk 'gd, in Box, a gen. of palme. The species C. oerifera, the Carnauba palm, is a native of the Brazile. On the lower surface of its leaves wax is secreted, and this is occasionally imported into this country under the name of Carnauba or Brazilian

Correg, ko'-ping (Du. kop, the head; Sax. cappe, a cap), in Arch., the layer of stones or brick that is placed on the top of a wall to form a finish to it, and placed on the top of a wall to form a finish to it, and to protect it from the weather. There are three kinds of coping; flat or parallel coping, which is generally placed on gable-ends of houses and walls of all kinds; feather coping, the stones of which are thicker on one side than on the other; and saddle-back coping, which slopes from the centre on either side. The coping should project beyond the surface of the wall over which it is placed, to prevent the rain from trickling down its sides.

COFFER, kop'-per, in Chem., symbol Cu, equivalent 31.75, spec. grav. 8.921 to 8.952. The symbol of this important metallic element is an abbreviation of its important metalic element is an abbreviation of its Latin name cuprum, which word is itself derived from that of the island of Cyprus (Gr. kupros), where it was first worked on an extensive scale. It was called Venus by the alchemists, who gave to it the symbol of that planet, 2. Copper is a hard, sonorous, ductile, and malleable metal, of a characteristic reddish-brown colour. Very thin films have been obtained, which were a fe a beautiful green colour by transmitted light. colour. Very thin films have been obtained, which were of a beautiful green colour by transmitted light. although of the natural colour by reflected light. is one of the best conductors of heat and electricity, and expands one part in 682 between the freezing and boiling points of water. By slow voltaic reduction, it may be obtained in cubes and octahedral forms, which are also taken by several deposits of native copper. The melting-point of copper is 1996° Fahr; and by exposing it to a very intense heat, it boils and volatilizes, burning with a brilliant green flame. Heated to redness in the open air, copper combines rapidly with oxygen; but even moist air at ordinary temperatures has but little effect on it. In sea-water it becomes gradually corroded by the formation of an exychloride of copper. Nitric acid oxidizes and dissoives it with great rapidity; sulphuric does not act on it at ordinary temperatures, but dissolves it rapidly if heated, sulphurous acid being evolved and oxide of copper formed, which unites with the excess of soid to form the sulphate. Hydrochloric acid dis-solves it with access of air; if the air is excluded, no action takes place. It is but little affected by the fixed alkalies; but, with access of air, ammonia slowly oxi-dizes it. The uses of copper are very important, large quantities being used for sheathing ships, and in the manufacture of boilers and utensils for domestic pur-With zinc it forms brass, and with different poses. With zinc it forms brass, and with different proportions of tin it forms bronze, bell-metal, gunmetal, and speculum-metal. Its oxides and salts are largely used as pigments and in pharmaceutical preparations. Copper unites with oxygen in four proportions:—1. The sub-oxide or dinoxide, Cu<sub>2</sub>O; 2, the protoxide or bluck oxide, Cu<sub>2</sub>O; 3, the binoxide, Cu<sub>2</sub>O; 2, the protoxide or bluck oxide, Cu<sub>2</sub>O; 3, the binoxide, Cu<sub>2</sub>O; and 4. eupric acid, the composition of which is not known. Bub-oxide of copper may be obtained in several ways:—1. By calcining the sub-chloride with carbonate of sods, and washing the residue; 2. by beating four parts of copper-filings and five parts of protoxide of copper in a close crucible; 3. by boiling adding potassa. By the first and third processes, the suboxide is obtained in a crystalline state. Subsuboxide is obtained in a crystalline state. Subsuboxide exide of copper is a feeble base, and its salts are un-important. Its principal use is in the manufacture important. Its principal use is in the manufacture of stained glass, to which it imparts a ruby-colour of great beauty. Protoxide of copper, CuO, is prepared by heating copper plates and turnings in a current of air, or by calcium nitrate of copper in an earthen crucible. It is a black powder, possessed of attong hygroscopic qualities. When strongly heated, it thuses, and parts with a portion of its oxygen, a compound of suboxide and protoxide being formed. Oxide of copper is easily reduced at a moderately high temperature by carloon, hydrogen, or organic matter.—a of great beauty. Pertocide of copper, CuO, is prepared by heating copper plates and turnings in a surrent of air, or by calcining nitrate of copper in an arthen crucible. It is a black powder, possessed of attenuers in the surrent of air, or by calcining nitrate of copper in an arthen crucible. It is a black powder, possessed of attenuers in the surrent of air, or by calcining nitrate of copper in an arthen crucible. When strongly heated, it flues, and parts with a portion of its oxygen, a consolide and protoxide being formed. Oxide pound of suboxide and protoxide being formed. Oxide of copper is easily reduced at a moderately high temperature by carbon, hydrogen, or organic matter,—a property which renders it peculiarly valuable in the ultimate analysis of organic bodies. It is also used to the surface of copper is occasionally found crystallized in tultimate analysis of organic bodies. It is also used to the surface of copper is occasionally found crystallized in tultimate analysis of organic bodies. It is also used to the surface of copper is occasionally found crystallized in tultimate analysis of organic bodies. It is also used to the surface of copper is occasionally found crystallized in tultimate analysis of organic bodies. It is also used to the surface of copper is occasionally found crystallized in tultimate analysis of organic bodies. It is also used to

water, but dissolves freely in soids, yielding very important salts. The hydrated axide, CuO2HO, inabitained by decomposing a solution of a copper salt with an excess of potassa. The pigment known as blue varietier consists of a hydrated oxide of copper. Boiled with water, it becomes black and anhydrius. It is soluble in ammonia, forming a deep blue solution. Binoxide of copper, CuO, has been obtained by the action of binoxide of hydrogen, or hydrated oxide of copper, It is a yellowish brown powder, easily decomcopper. It is a yellowish-brown powder, essily decomposed into oxygen and oxide of copper by heat or acids, Cupric acid, the formula for which has not been detertermined, is known only in combination with potass and is formed when fluely-divided copper is heated to reduess with caustic potsah and nitrate of potasts. Digested in water, the mass yields a blue solution, supposed to consist of cuprate of potasts. The salts of copper are characterized by their green or blue colour. They are nearly all soluble, and have a strong, disagreeable, metallic taste, acting as poisons. on the human system. The symptoms of poisoning by copper are violent and irrepressible purgings and vomitings, followed by exhaustion and death. The best antidote is albumen, or white of egg, with which they form an insoluble and almost inert compound. In medicine, sulphate of copper is used as a tonic, and antispasmodic in cases of dyspepsia and Asiatic cholera. It is also used as an outward application to wounds which present the granulated appearance known as "proud flesh." In five-grain doses, sulphate of copper acts as a powerful enetic. The other salts of copper are but seldom used. The most other saits of copper are but seidom used. The most characteristic reactions of copper saits are as follows: Ammonia in excess gives a dark blue solution; yellow prussiate of potash gives a red-brown precipitate. A strip of bright metallic iron precipitates copper from acid solutions in a metallic form. Of late years, copper has been used somewhat extensively to give a bright green colour to pickles and preserves. Its presence may be readily detected by incinerating the suspected article, washing the ashes in water, and filtering. If, on the addition of liquid ammonia, the solution strikes a deep blue colour, copper is present. Oxide of copper forms four compounds with acetic acid: neutral acetate (known in commerce under the name of verditer, which see), subsesquiacetate, diacetate (or verdigris, which see), and the triacetate, which is the most stable of the acetates of copper. Copper forms two chlorides, two simple compounds with evanogen; Wurtz obtained a compound termed hydride of copper; and there is another important salt termed nitrate of copper. The copper of commerce is very nearly pure, containing only traces of arachie, iron, lead, tin, and silica. Copper is employed chiefly in the sheathing of ships, to protect them from the action of the sea-water. It is also used very largely in the construction of small boilers and culinary vessels. Copper-plates are used in engraving, the impression being very sharp and delicate. The most important alloys of copper and zine are brass, Dutch gold, pinchbeck, and tombac. Brass varies in composition according to the purpose for which it is to be used. It generally consists of twothirds copper and one of zinc, with traces of lead and tin. Formerly, it was the custom to fuse the zinc ore and the copper together; but nowadays it is considered better to prepare brass by combining its constituent metals in proper proportions. Tombac is about fifteen per cent. poorer in copper. The principal alloys of copper and tin are bronze, gun-metal, bell-metal, and speculum-metal. The alloy known as argentum, packfong, or German silver, consists of two parts of copper, one of nickel, and one of zinc. The copper and zinc are first fused together, and the zine

### Copper Pyrites

Lake Superior is a vein of metallic copper associated with silver, two feet in thickness. The commencet ore of copper is copper pyrites, which is the ore found in Cornwell, from which more than two-thirds of the copper used in Great Britain is obtained. After being sorted and sifted, it is sent to Swanses to be smelted. North America and Saxony also supply this ore. The Australian ore, large quantities of which are annually imported, is a mixture of the green and blue carbonate. and contains from 25 to 30 per cent. of metal, the average of Cornish pyrites containing only 84 per cent. Cartain ores found in Chili are galuable from the amount of silver they contain. The red and black oxide also occur in Cornwall, Siberia, Brazil, and Germany.

COPPER PTRITES, in Min., an important ore of copper, occurring as a double sulphide of iron and copper, occurring as a double sulphide of iron and copper, Cu<sub>2</sub>S.F.S., in various parts of the world. Copper pyrites have a brassp lustre, and are found generally in amorphous masses with a conchoidal fracture; sometimes they occur crystallized in tetrahedra. The variety called peacock copper ore contains a very large per-centage of copper.

COPPER-SMELTING. (See SMELTING.)

COPPERAS, kop-per-us (from Germ. kupper-wasser, copper-water).—This term is applied, with the prefixes blue and green, to the sulphates of copper and iron

respectively.

COPPRED, kop'-perd, in Mar., is a term employed to denote a ship whose bottom is cased with copper, in order to prevent the worms eating into the planks or To keep dirt from accumulating there. The practice of copper-sheathing was introduced about the year 1758. COPPER-EASTENED.—When the heads of all the bolts and other metal-work in the exterior of a ship's hull

are formed of copper, she is said to be copper-fastened. This is done because, if made of iron, they would corrode

when the vessel is copper-sheathed.

when the vessel is copper-sheathed.

COPPERFLATE PAINTING is performed at what is called a rolling press. In the process of printing, the plate of copper from which the impression has to be taken is raised to the temperature of about 180°, by placing it in an iron box in which steam circulates. Copper-plates were formerly heated by placing them copper-places were formerly heated by placing them over burning charcoal, thus causing the trade to be very injurious to the health of the workmen. After the plate is heated sufficiently, the printer dabs a small quantity of ink on the face of it with a rubber made of linen rags. He then removes the plate from the source of heat, takes off some of the superfluous ink with a piece of canvas, next carefully rubbing the face of the plate with both hands in succession. To accelerate the wining, he dips his hand from time to time in whiting. The chief art of the printer is to remove every particle of the ink from the plain surface, and yet not disturb the ink in the engraved parts. When properly finished, the plate is laid on the plank of the press, and the damped paper which is to receive the impression is laid over it, with two or three folds of flannel or blanket above. The plate is then pulled through the rollers of the press, and the required impression obtained.

COPRIDE, kop'.ri-de, a fam. of four-winged insects allied to the Scarabaæ. The name is from the Greek word for dung (kopros), in which these beetles are ge-

nerally found.

COPROLITES, kop'-rol-ites (Gr. kopros, dung; lithos, stone), are the excrements of animals found in a fossil state in the secondary and tertiary strata. They consist chiefly of the voidings of saurians and sauroid fishes. The true nature of coprolites was first discovered by their occurrence near the region of the intestinal tube in the bodies of several fossil ichthyoautestinal tibe in the bodies of several fossil ichthyo-sauri. Scales, bones, teeth, and other parts of undi-gested food, are often found in them, and occusionally they are found exhibiting the spiral twisting noticeable in the excrement of some living fishes. Coprolites contain a considerable proportion of phosphate of lime, for which reason they are largely employed in the manufacture of artificial manures.

facture of artificial manures.

COPTIC LANGUAGE, kop'-tik, is the language of the ancient Copts, or that which was in use in Egypt after the introduction of Christianity. What relationship it bore to the more ancient language of that country it was the country in the more ancient language of that country is is impossible to determine. The written character is

# Copuls

Greek, with an addition of eight other letters to express sounds peculiar to the Coptio, and many Greek words have been introduced with Christianity. There are two principal dialects of the Coptio,—the Sahidu, are Upper Egyptian, and the Memphetic, or Lower Egyptian. The former contains a greater number of Greek tian. The former contains a greater number of creek expressions, but the latter appears to be the more polished. There is a third dialect,—the Bashmuric, which was spoken in the Delta, but of which only a few fragments now exist. It is interesting from its supposed resemblance in some points to the language of the hieroglyphics. The Coptic literature is by no means rich or valuable, consisting for the most part of translations of the sacred Scriptures, lives of saints, homilies, and some Gnostic works. The translations of the Bible were probably made about the end of the 3rd or beginning of the 4th century, and follow, as far as the Old Testament is concerned, the Septuagint version. The Coptic language has not been spoken in Lower Egypt since the 10th century, but it lingered for some centuries later in some parts of Upper Egypt. It is still, however, employed by the Copts in the religious worship; but the lessons, after being read in Coptic, are explained in Arabic.

COPILS, kept-tis (from Gr. kepte, I cut), in Bot., a gen. of plants belonging to the nat. ord. Ranunculaceas. The species C. trifoliata, commonly called gold thread, is a native of North America, and is much prized for its root, which is a pure and powerful bitter, and forms an excellent stomachic and tonic. The root of C. Teeta is found in the bazaars of India, under the names of mishmee bitter and mahmira. It is intensely bitter, and

is a very valuable tonic.

Corrs, kopts, the name given to the Christian descendants of the ancient Egyptians. The name is generally believed to be derived from the city of Coptos, in Upper Egypt, to which, during the persecutions that took place under the Roman emperors, many of the Christians had fled for refuge. In Egypt they are called Kibl, which some are inclined to believe to be the root of the name Egypt. The number of Copts in the root of the name Egypt. The number of Copts in the country at present is not more than 150,000, or about a fourteenth part of the entire population, and about 10,000 of them live in Cairo. They are not of large stature, have black eyes, rather curly hair, and in several other respects resemble the ancient Egyptians, from whom they have inherited also the custom of circumcision. Their dress very much resembles that of the Moslems; but they are usually distinguished by a black turban. In character they are accurally gloomy descriptly, and avariance they are generally gloomy, deceifful, and avarious. They have always been distinguished for their expertness in figures, in consequence of which many of them fill important posts throughout the country, and have acquired great influence. In religion they are generally monophysites of the Jacobite sect, only a small portion of them being united either with the Greek or Roman church. They ascribe their conversion from heathen-ism to St. Mark, whom they regard as the first patri-arch of Alexandria. Their present patriarch is still said to be "of Alexandria," though he resides at Cairo. Besides him, they have a metropolitan of the Abys-Heades him, they have a metropolitan of the Abysainians, bishops, arch-priests, priests, deacons, and monks. The patriarch is always chosen from the monks of the convent of St. Anthony, either by his predecessor or by lot, and is not permitted to marry. He nominates the metropolitan of Abyssinis, who resides in that country. There are twelve bishops. resides in that country. There are twelve bisho The Copts are very strict in their religious observant and hate other Christian sects more than they do the Moslems. They practise baptism by immersion, unc-tion, and exercism; have auricular confession, and celebrate the Lord's Supper with leavened bread which has been dipped in wine. They fast regularly on Friday, and observe it with great strictness. Their monks and nuns lead a very strict life. The Copts have many schools, but only for boys, who there learn the psalms, gospels, and the apostolic epistles in Arabic, and then the gospels and epistles also in Coptic. The Coptic, however, is not taught grammatically, nor is it any longer a spoken tongue. - Ref. Conversations Lexikon.

COPULA, kep'-u-la (Lat., a band), is the name given in Log. to the word or words which connect the predicate and the subject of a proposition, which indicate

# Copyhold

that the predicate is affirmed or denied of the subject es the copula is contained in the predica as, The fire burns; but in strict logic is and is not, or some other part of the verb to be, are the only copulas permitted; as, The fire is burning; John is not at home.

COPYHOLD, kep'-s-hold, is a tenure for which the tenant has nothing to show but the copy of the rolls, made by the steward of the lord's court, on such tenant being admitted to any lands or tenements within a manor that time out of mind, by use and custom of the manor, have been granted or demised to such as are entitled to take the same in fee or fee-tail, for life, years, or will, according to the custom of the manor by copy of court roll of the manor.

COPYING-MACHINE, kop'-e-ing, a contrivance by produced without having recourse to transcription. A copying-machine generally consists of a flat bed, upon which rest the letter to be copied and the paper for the duplicate. Above these is a fixt plate, called a platten, which, by means of a screw or lever, is made to produce the necessary pressure. The ink with which the letter is written contains a certain amount of sugar or treacle, which is transferred to the paper laid upon it by the pressure exerted. The copy made is, of course, reversed, but the paper is purposely made thin, in order that the writing may be read through it. that the writing may be read through it. taken trivances have been invented for procuring the necessary of pressure, but the simple serew and Various consary amount of pressure, but the simple screw and lever appears to be the best of them all. The manifold-writer may be described under this head. It simply consists of a number of sheets of paper blackened with some composition that will come off when pressed hard, but will not move at a slight degree of pressure or friction. Blank sheets of paper are inserted between these, and the writing is performed with a hard stylet made of steel or agate, the whole being placed on a smooth copper or pewter plate. (See also Panta-GRAPH.)

COPYRIGHT, kop'-e-rite, is that right which the law allows an author or his assigns of printing and reprint-ing his own original work. The Roman law contains no recognition of the right of property as regards the productions of literature; neither with us in England was the right of authors in this respect clearly ascerwas the right of authors in this respect clearly ascer-tained until a comparatively late period of our legal history; but in the reign of Queen Anne it became at length the subject of positive regulation, and subse-quent enactments were applied to it. It is now mainly regulated by the 5 & 6 Vict. c. 45, which provides that the copyright of every book (under which word is included, in the construction of the act, every volume, part, or division of a volume, pamphlet, sheet of letter-press, sheet of music, map, chart, or plan sepa-rately published which shall be published in the life-time of its author, shall endure for his natural life, and for seven years longer; or, if the seven years shall and for seven years longer; or, if the seven years shall expire before the end of forty-two years from the first expire before the end of forty-two years from the first publication, shall endure for such period of forty-two years; and that, when the work is posthumous, the copyright shall endure for forty-two years from the first publication, and shall belong to the proprietor of the author's manuscript. If the work he unlawfully printed within the British dominions, an action for damages must be brought within twelve calendar months; and, if unlawfully reprinted in any place out with a first hadminions and imported into the United of the British dominions and imported into the United Kingdom, it may be seized as forfeited by any officer of the customs or excise, and the offenders are liable to penalties. The title of the work must be registered at Stationers' Hall before an action can be brought for the infringement. The act empowers the judicial committee of the privy council to allow the proprietor of a deceased author's work to publish the work, subject to such conditions as they may think fit. Besides the a disceased author's work to publish the work, subject to such conditions as they may think fit. Besides the remedy by action, the courts of equity will (after the registration) interfere by injunction to restrain an arkingement of the right. An assignment of the copyright properly registered at Stationers' Hall is as effectual as it made by deed. Protection does not extend to the work if it be immoral, blasphemous, or saditions in its tendency, or if it be defamatory of private character, or if (with a view to defraud the public it is published as the work of one who is not in truth

### Corel Rest

the author. The sole liberty of printing and publish ing (except in unlicensed places) al lecte to the lecturer; and the author of dramatic pieces and musical performances has, as his own property; the sole liberty of bringing them out upon the stage. The law also recognizes a species of copyright in engrand and recognizes a spones of copying in engrange and classified also in designs for articles, whether of ornament or utility. And by the law regulating international copyright, the And by the law regulating intermetional conjuright, the copyright of works, as well in the language in which they are written, as of translations, is reserved to foreign authors, under certain regulations, one of them being the registration at Stationers' Hall; and this international protection extends not only to books and prints, but also to articles of sculpture and other works of art. (See 5 & 6 Vict. c. 45; 7;& 8 Vict. c. 12; 8 & 9 Vict. c. 93; 10 & 11 Vict. c. 95; 15 & 16. Vict. c. 12; 13 & 14 Vict. c. 104; and 21; 22 Vict. c. 70.) (See further, as to protection of inventions, Patent, Lutters.) By the Copyright (works of art) Act, 1862, protection is extended to artists. It is thereby enacted that the author (being a British subject, or resident within the dominions of the crown) of ject, or resident within the dominions of the crown) of every original painting, drawing, and photograph, which shall be, or shall have been made, either in the British dominions or elsewhere, and which shall not have been disposed of before the commencement of the act (29th July), and his assigns, shall have the exclusive right of copying, reproducing, and multiplying the same for the term of his natural life, and seven years after his death. If, on sale, he wishes to reserve the copyright, he must have an agreement in writing to that effect, or the right will belong to the purchaser.

The act is not to prejudice the right of any person to copy or use any work in which there shall be no copyright, or to represent any scene or object, notwithstanding there may be copyright in some representa-tion of such seene or object. The work must be entered at Stationers' Hall, the charge for which is to be one shilling; and certain enactments of the 6 Vict. are to apply to the entry. The penulty for each offence against the act is £10, and foreiture of the copy. The International Copyright Act of the 7 & 8 Vict. forms part of the act.

COQUILLA NUTS. (See ATTALIA.)
COBACLE, kor'-ä-kl (Celtic, curach), a light boat or
canoe, constructed with a framework of wood covered with skins. Coracles were used by the ancient Britons from the most remote times. Julius Cosar built some after the British model: the keel and gunbuilt some after the British model: the keel and gun-whales were of light wood, and the sides of wicker, covered with hides. The general size of a coracle was about four feet long and three wide, its shape being oval. It held only one person, who propelled it with a paddle, and on land it was carried with case upon the shoulders from place to place. The coracle is still in use in some parts of Ireland, especially on the coasts of Donegal and Clare. It is also used on the Severe, in England.

CORAL REEF, kor'-al (Gr. korallion, Fr. corail, Ger. riff, a reel), a term applied by naturalists, as well as by mariners, to any connected mass of coral structures, whether trending away in long partially submerged ledges, encircling islands like breakwater barriers, or rising as low ring-shaped islets above the waters of the ocean. In almost all tropical seas, incrusting patches or small banks of living coral are to be found along the shores, wherever they consist of hard rock and the water is quite clear. In the In-dian and Pacific oceans, however, far away from any land, huge masses of coral rock rise up from vast and unknown depths just to the level of low water. These masses are often unbroken for many miles in length and breadth, and groups of such masses, separated by small intervals, occur over spaces some-times of 400 or 500 miles long by 50 or 60 in width. One of the greatest formations of coral rock is along the north-east coast of Australia. (See BARRIKE REEF.) The reef masses consist of living corels only at their upper and outer surface; all the interior is composed of dead corals and shells, either whole or in fragments, and the calcareous portions of other marine animals. The interstices of the mass are filled by calcareous sand and mud derived from the waste and débris, the wear and tear of the corals and shells, and by count.

200

### Corbel

less myriads of minute organisms, mostly calcareous also. The surface of a reef, when exposed at low water, is composed of solid-looking stone, which is often capable of being split up and lifted in alaba, bearing ao small resemblance to some of our oldest limestones. The slabs, when broken open, are frequently found to have a semi-crystalline structure internally, by which the forms and the organic structure of the orals and shells are more or less disguised and obliterated. The raised coral-reefs in the islands of Timor and Java are often internally as white and frishle as chalk. Darwin states that the principal reef-builders are the madrepores, astrans, portles, menadrines, and nullipores, at moderate depths, and the militares are all others and other delicate. the milispores, seriatopores, and other delicate forms, at depths from fifteen to twenty fathoms,—the great at depths from fitteen to twenty inthoms,—the great field of coral development thus lying between low water and twenty inthoms.—Ref. Darwin On the Structure and Distribution of Coral Reefs; Voyage of H.M.S. Fly; Dank's Report on the Geology of the United States Exploring Expedition.

CORBEL, kor'-bel (Ang.-Norm.), in Arch., the name given to blocks of stone projecting from the surface of a wall to support the machicolations of towers (see MACHICOLATION), or the ends of the beams of the floors in old castles. The beams which form what is floors in old castles. The beams which form what is called an open roof in churches and large halls are often supported on carved corbels. The stones which support the bartizans (see Bartizan) at the angles of towers, jutting out in layers one above another, are also called corbel-stones, and stones which project in this manner are spoken of as "corbelling out."

Conchonus, kor'-kor-us (from Gr. koreo, I purge, in allusion to the laxative qualities of C. olitorius), in Bot., a gen. of plants belonging to the nat. ord. Tiliacca. The most important species is C. vapudaris, the jute-plant, a native of India. The fibre called jute, or jute-hemp, is obtained from the bark. It is now imported in enormous quantities into this country, and is employed for making coarse bags, and as a foundation for inferior carpets. It is also frequently mixed with silk in the manufacture of cheap satin fabrics. It does not appear to be well adapted for norms. It does not appear to be wen anapted for cordage, because it will not bear exposure to wet. In India it is used chiefly for the purpose of making coarse canvas called quanty, which is the common material for bags employed in packing raw produce. The species C. olitorius, commonly called Jews mallow, is used in some parts of the world as a pot-berb. In Panama the leaves of C. mompowensis are employed as a substitute for Chinese tea.

CORDELIEUS, kor-de-leers', was the name given to the strictest branch of the Franciscan friars, on account of their wearing a knotted cord for a girdle. were originally called minor friars, and were established towards the end of the 14th century. There are said to have been at one time in France no fewer than 284 male and 123 female convents of Cordeliers. During the French revolution of 1789, a political society assumed this title from the circumstance of its meetings being held in an old Franciscan convent. It was opposed to the Jacobins, and was of great influence, numbering among its members Danton, Desmoulins, Marst, and others.

Marst, and others.

Condiace kor-de-ai'-se-s (in honour of Cordus, a German botanist), in Bot., the Cordia or Sebesten fam., a nat. ord. of tropical trees in the sub-class Corolliflers. The fruits of many species are edible; as those of Cordia mayar and latifolia, known in India as Sebastens or Sebasten plums; those of C. abyssinica, commonly called the Wanzey, a native of Abyssinica; and those of Varronia rotundifolia, which are used to fatten cattle and poultry. The order consists of elevan cases in which there are about 180 known species. genera, in which there are about 180 known species.

CORDIALS, OF LIQUEURS, kord sides (Fr. Sp. cordial, from Lat. cor, the heart), are made by flavouring rectified apirit with different essential oils, such as aniseed, earsway, clove, peppermint, &c., and adding a portion of syrup sufficient to neutralize the burning taste of

the spirit.

Cordences, kor'-di-seps, in Bot., a gen. of Fungi, including many species which are very destructive to living plants and animals. The disease called ergo, which occurs in the grains of rye and other grasses, is produced by O. purpures. (For Ergot of Rye, see 563

# Corinthians, Epistles to

SHOALE.) Caterpillars are frequently killed by other species growing in them. The remains of the exterpillar, with the developed fungus of the species C. inensis, is a highly esteemed drug in China, where it is much used as a tonic.

TO TRANSPER. (See CORIANDRUM.)
CORTANDRUM, kor-e-iin-drum (from Gr. koris, a.bug,
in allusion to the smell of the leaves), in Bot., a gen
of plants belonging to the nat. ord. Umbelijfera. The species C. activum, the coriander, has long been cultivated for its fruits, improperly called seeds, which are used in the East for flavouring dishes and curriepowder, and in Europe for the purposes of the distiller, confectioner, and pharmaceutist. They have a peculiar odour and warm aromatic taste, due to the presence of a yellowish-coloured volatile oil.

CORIARIACER, ko-re-ar-e-ai'-se-e (Lat. corium hide), in Bot., the Coriario fam., a nat. ord. of di-cotyledonous plants, in the sub-class Thalamiflore. There is but one genus, which includes eight known species, natives of the south of Europe, Chili, Peru, New Zealand, and Nepaul. The order appears to be most nearly related to Ochnaces, with which it agrees in having its carpels distinct, and placed on an enlarged disk or gynophore; but it is distinguished from that order by its opposite leaves, by sometimes having polygamous flowers, by the persistent fleshy petals, by the absence of any style, and by its long linear distinct stigmas. The plants are to be regarded with distinct stigmas. The plants are to be regarded with suspicion, as they have sometimes produced poisonous effects: the fruits of some, however, are edible. The leaves of Coriaria myrtifolia have been used on the continent to adulterate senna, though such leaves are known to be poisonous. They may be at once distinguished from senna-leaves by their two sides being equal and symmetrical at the base, while those of seuna are unequal. C. myrtifolia and ruscifolia have been employed to produce a black dye: the fruits of both

species are very poisonous.

CORINTHIAN ORDER. (See ARCHITECTURE.) CORINTHIANS, EPISTLES TO THE, kor-in'-the-ans, are two epistles of the apostle Paul addressed to the church at Corinth, and forming part of the canonical writings of the New Testament. In order clearly to comprehend the scope of these epistles, it is necessary to glance at the circumstances of the people to whom they were addressed. Christianity was first planted at Corinth by the apostle Paul himself during a residence there of about eighteen months, between A.D. 51 and 53. After Paul's departure from Corinth. Apollos. an eloquent man and mighty in the Scriptures, came and preached the gospel there with great success, water-ing what the apostle had planted. Other teachers of Christianity also came among them, and the Church came to be divided into different sects,—some declaring for Paul, others for Apollos, some for Cephas, and some for Christ. The converts, too, were partly Jews and partly Gentiles; the former contending strenuthe observance of Jewish ceremonies, the latter giving way to the idolatrous and lascivious practices of the heathens. When the apostle Paul received information of this state of matters, he wrote to them his First Epistle, the contents of which naturally divide themselves into two distinct parts,—the one being intended to remedy the disorders and abuses that had crept into the Claurch, the other being in reply to certain questions which the Church had sub-mitted to him for his decision; as, concerning matrimony, concerning the lawfulness of eating things sacrificed to idols, and touching the resurrection of the dead. This epistle produced very different effects in the Church. Many were led to amend their conduct, and to greater vigilance and seal against the errors into which they had fallen; while others were led to cast imputations upon the spostle, and to accuse him of levity, pride, arrogance, and of being personally contemptible. The great object of the Second Epistle was, therefore, to defend himself against these imputations. He enlarges on his spiritual office, enumerates his sufferings and disasters, recounts his labours, and details his successes. The great oratorical power of this epistle has always been much admired. The various emotions that agitated the mind of the apostle when writing it are expressed with great power. These, as well as his elegance of diction, powers of

#### Cork

persuasion, and force of argument, are all admirably discussed and illustrated by Professor Royaards in his discussed and illustrated by Professor Royaards in his "Disputatio inauguralis de altera Pauli ad Corinthios Epistols," IS18. The former of these epistles is gene-rally believed to have been written about A.D. 57, the latter about 58. The authenticity of either has scarcely even been questioned; but much discussion has arisen as to whether the apostle had addressed to the church at Corinth an earlier epistle than either of these, reterred to in 1 Cor. v. 9, in the words, "I have written fo you in an epistle." Those who are of opinion that there was no other epistle, maintain that the reference is to the one he was then writing .- Ref. Horne's In-

traduction to the Holy Scriptures.

CORK, kork (Lat. cortex, rind, shell; Germ. kork). In Manuf., cork is the outer bark of the evergreen oak, a tree growing in Portugal, Spain, Italy, and France. The largest quantity of cork is obtained from France. The largest quantity of cork is obtained from Spain and Portugal; the smallest but best portion coming from France. The principal use of cork is for the stoppers of bottles, its softness and elasticity rendering it psculiarly valuable for this purpose. Being esceedingly light, it is used for the floats of fishermen's nets. Cork-cuttings, till lately a waste product, have received important applications in the manufacture of mattersess and life-invaronces. In a manufacture of mattresses and life-preservers. In a state of coarse powder, it is used, in conjunction with india-rubber and gutta-percha, in the manufacture of kamptulicon, or elastic floor-cloth. (See Kamptulicon) con.) Cork, when treated with nitric acid, yields

CORM, when the see. See also QUERCUS).
CORM, korm (Gr. kormos. a stump), in Bot., a solid underground stem, which does not spread by sending out roots, but remains in a rounded form. It occurs in the tulip, crocus, and in many other monocotyledo-nous plants. It is distinguished from a root by producing annually small corms, or thickened branches.

It differs from a bulb in being solid. (See Bulb.)
CORMODITYES, korm'o-files, in Bot., plants having
stems, as distinguished from Thallophyles, or those
which simply form cellular expansions of various kinds, to which the term thallus is applied. Cormophytes are divided, according to the internal structure of their stems, into three great classes, called respectively Exogens or Dicotyledons, Endogens or Monocotyle-, and Acrogens or Acotyledons.

CORMORANT, kor-mor-ant (Fr. cormoran).—This bird is very widely diffused, and inhabits the New as well as the Old continent. Its length is from twenty-seven to twenty-nine inches. Under the throat there is a

whitish collar, reaching as far upward as the eyes. Top of the head, neck, breast, and lower parts greenish black; upper part ashy brown, bordered by a band of glossy greenish black; quill and tail-feathers black; bill blackish ash; feet black. This is the bird's

CORMOBANT.

winter plumage. In the spring the occiput and a part of the nape of the neck are adorned by a creat of long green feathers, and the collar round the neck changes to the purest white. "The young, when first hatebed," writes Mr. Selly, "are quite naked, and very ugly, the skin being of a purplish black. This, in six or seven days, becomes clothed with a thin black down; into the feathered plumage is not perfected in less than five or hit weeks. I have repeatedly found that, when the search of the search only half-fledged, they im-

#### Corn Laws

mediately plunge beneath the surface, and endeavour to escape by diving. This they will do to a great distance, using their imperfect wings and pursuing their submarine flight in the same manner, and almost with as much effect, as their parents." The small spising from the cormorant is said to be so offensive that the Greenlanders will not touch it. If buried in the ground for about twenty hours, however, the offensive odour abates, and they may be esten by persons of strong appetites. It is found on the Tern Islands, where its nest is entirely composed of sea-weed, which is frequently heaped up to the height of two feet. In this rough nest are deposited from three to five eggs, of a pale bluish white, with a rough surface. Cormorants were formerly trained in England to catch tish for the table. When so employed, their necks were encircled. by a leather thong, to prevent them from swallowing the catch. The Chinese cormorant (Phylacrocorax siensis), or Leutze, as the Chinese call it, is commonly bred and instructed in the art of fishing.

CORN, koarn (Ang. Sax.), a term generally applied to all seeds used in making bread, especially the seeds of the cerealia. The principal seeds of this kind in temperate climates are wheat, rye, oats, and barley; while those of warm climates are maize, rice, and millet. In a more restricted sense the word corn is applied to that particular grain of a country which is most largely used in making bread. In England corn refers to wheat, in Scotland to oats, and in America to maize.

COEN LAWS and COEN TRADE.—From the great importance of corn as an article of food, it is scarcely to be wondered at that it was so long subject.

scarcery to be wondered at that it was so long subject to government interference and restrictions in this country. From the period of the Conquest down to the year 1436, the efforts of the government were directed to prevent its exportation out of the country, while, at the same time, its importation was permitted. The object was to provide an abundant supply of this prime necessary of life at as low a rate an assistant that intractable science of reditted as possible; but in that intractable science of political economy, the means adopted to produce a certain result have often been found to have a contrary effect, Agriculture was neglected, because the farmers could not obtain a remunerative price for their produce. 1436, therefore, with a view to stimulate home production, an act was passed authorizing the exportation of wheat whenever the home price did not exceed 6s. 8d. (12s. 103d. of present money) per quarter, and of barley when the home price did not exceed 3s. In 1463, another act was passed prohibiting the importation of corn from abroad until the home price exceeded that at which exportation ceased. On account of the fluctuating policy of the times, however, these laws were in a great measure inoperative. Nominally, they continued in ferce till 1562, when the prices at which continued in ferre in 100, when the prices as more exportation night take place were extended to 10s. per quarter for wheat, 8s. for rye, and 6s. 8s. for pharley. Nine years inter (1571) an act was passed which declared that the lord presidents and councils and the justices of assize should, within their respec-tive jurisdictions, consult with the inhabitants as to the cheapness and dearth of any kinds of grain, and fix annually the average prices by which exportation should be governed within their several limits. Corn might thus be exported at all times to friendly countries when proclamation was not made to the contrary, subject to a poundage or customs duty of 1s. per quarter on all wheat exported; and if exported under special license, and not under the act, the duty was 2s. per quarter. In 1593, another act was passed permitting exportation on paying a duty of 2s. per quarter on wheat and 1s. 4d. on barley and malt, whenever the price did not exceed 20s. and 12s. respectively. In 1604 the price was again raised to 26s. 8d. per quarter of wheat; and in 1623, to 32s. for wheat and 16s. for barley and malt. Besides the various acts passed for regulating the foreign trade in corn of this country, there were various enactments interfering with it within the kingdom. Under the impression that the injurious effects of dearths, which were then of frequent occurrence, were much aggravated by dealers in corn buying it up sad withdrawing it from the market, and that, if corn were purchased by the consumers directly from the growers, it would be obtained cheaper, as the profits of the dealers would

thus be saved, various acts were passed against the buying of corn in one market with the view of sell-ing it again in another, called expressing (which see), declaring such an offence to be punishable by fine and declaring such an offence to be punishable by line and imprisonment. During the troublous times of the civil war, the minds of the people were too much agitated to pay much regard to the corn trade; but, on the restoration of Charles II. a new scale was introduced. Wheat was permitted to be exported when the price did not exceed 40s, per quarter, barley and malt 20s., oats 16s.; the export duties being on wheat 20s. per quarter, barley and malt 10s., and oats 6s. 8d. By the same act the import rates or duties were fixed as Callows. On wheat when the price did not exceed 44s. follows: on wheat, when the price did not exceed 44s. per quarter at the place of importation, 40s. a quarter; when it exceeded that rate, 0s. 8d. a quarter; barley and malt, when the price did not exceed 30s. at the place of importation, 26s. 8d.; and when it exceeded that rate, 5s. per quarter. Of course, these high duties seted as a virtual prohibition of the trade. Three years later, the corn trade again became a subject of legislation. By 15 Car. II. c. 7, it was declared that when the price of wheat does not exceed 45s, per quarter at the havens or places of shipment, barley and malt 28s., and oats 13s. 4d., then it shall be lawful for any person or persons to transport said corns or grains from such places to any parts beyond the seas, subject, however, to the same rate of duties as had been fixed by the previous act. It was further declared that when the prices of said corns and grains do not exceed the above-mentioned rates at the port or haven where any of them may be imported, they shall be subject to the following duties; viz., wheat 5s. 4d. per quarter, barley and malt 2s. 8d., and oats 1s. 4d. This act further declared, that when the price of corn or grain did not exceed the above rates, then it should be lawful for any person or persons to buy in open market, and to lay up and keep the same, and afterwards to sell it without incurring any penalty. In 1670 a duty of 16s. was imposed upon all wheat imported into this country when the price was at or under 53s. 4d. per quarter in this country, and 8s. when above that price and under 80s., at which last importation was free. In order to determine accurately the price of grain at the various ports wherein foreign corn might be imported, it was enacted in 1685 that justices of the peace in the several counties may, at quarter sessions, by the oatla of two persons duly qualified (i. e. possessed of estates of a certain value and not being corn-dealers), determine the prices of the several kinds of grain to be certified to the principal officer of the customs in the several to the principal officer of the customs in the several counties for his rule and regulation. The average price of wheat per quarter for the ten years from 1650 to 1670, 48s. 10d.; from 1660 to 1670, 48s. 10d.; from 1670 to 1680, 50s. 8d.; and from 1680 to 1685, 44s. 3d. The increasing power of the agricultural party in the state is evident from the various legislative enactments that were made to protect their interests. This was still further evident by the act passed shortly after the accession of the prince of Orange to the throne in 1688, by which a bounty of 5s. was granted for every quarter of wheat exported when the price was at or below 48s., and other kinds of grain in proportion. Subsequently, by 11 & 12 Will. III. c. 20, all previous duties on the exportation of corn were abolished, while the duties exportation of corn were abolished, while the duties and restrictions upon the importation of corn continued unabated. From 1697 to 1773, the total amount of bounties paid on exports out of the public revenue was 26,237,176. In the four years ending 1691, the price of wheat averaged 27s. 7d. the quarter, being lower than at any period during the century; but in the four years preceding 1699 it reached 56s. 6d. "In the twenty-three years from 1692 to 1715," says Mr. Tooke, in his "History of Prices," "there were eleven bad seasons during which the average price of wheat was in his "History of Prices," there were cloven bad seasons, during which the average price of wheat was 45s. 8d. the quarter; in the fifty years ending 1765 there were only five deficient harvests, and the average price for the whole half-century ranged at 34s. 11d.; and taking the ten years ending 1751, during which the and taking the ten years ending 17st, during which the crops were constantly above the average, the price of wheat was only 29s. 23d. the quarter." In considering the effects of the bounty, it is not to be forgotten that prices were gradually falling before it was granted, and it was with the avowed intention of checking this fall that it was obtained. There can be little doubt,

however, that, by atimulating cultivation to too great an extent, it had counteracted the intention for which it was framed; and it was not till sixty or seventy years after its introduction that, by the increase of the population, the consumption came to be in some measure proportioned to the enlarged produce of the agriculturists. After the year 1750, when the exports of all kinds of grain amounted to 1,067,778 quarters, the quantity exported rapidly decreased, and in 1760 it was only about 600,000 quarters. After the peace of Paris, in 1673, the march of improvement was much accelerated, and the price of wheat rose to an unusual height. In 1773 an act was passed declaring the bounty and exportation to cease until wheat should be 44s, and barley 22s. a quarter; and allowing foreign wheat to be imported on paying a nominal duty of 6d, whenever the home price reached 48s, a quarter. The object of these regulations was to maintain, as far as possible, a level rate of 48s., which was assumed to be a fair price both for grower and consumer. The landowners raised a loud clamour against this law; and at length, in 1791, they succeeded in obtaining an act raising the price at which importation was allowed at 6d. a quarter to 54s., a duty of 2s. 6d. being imposed when the price was between 50s. and 54s., and a prohibitory duty of 24s, 3d, when below 50s. In 1804 a prohibitory duty of 24s, 3d. per quarter was imposed on all wheat imported when per quarter was imposed on all wheat imported when the home price was at or below 63s.; between 63s. and 66s. a middle duty of 2s. 6d.; and above 66s. a nominal duty of 6d. The price at which bounty was paid on exportation was changed to 40s.; but grain might be exported without bounty so long as the price did not exceed 54s. In 1813 and 1814 committees of both houses of parliament were appointed to examine and report on the state of the corn trade; and in 1815, after much opposition, an act was passed allowing the free importation of corn from foreign countries, in order to be warehoused or re-exported, but forbidding the importation for consumption unless the prices were, for wheat 80s., for barley 40s., and for oats 26s. From the British colonies, however, grain might be imported for consumption when the prices were, for wheat 67s, barley 33s, and oats 22s. In this year also the bounty was abolished, though since 1792 the price at home had been so high that none could have been along and the state of the sta none could have been claimed. In 1816 and 1817 the harvests were deficient, and the prices were raised above these limits, so that a large quantity of corn was imported free of duty. The year 1822 yielded an abun-dant harvest, and the prices fell lower than they had been at any time since 1709. In 1823 the act of 1815 was so far modified as to allow of grain being imported for home consumption when the prices were, for 70s., barley 35s., oats 25s. per quarter, and from British colonies when at 53s., 30s., and 20s. respectively. In order to prevent any violent reaction from a large supply of grain being suddenly thrown upon the market, a duty of 17s. a quarter was to be laid upon all wheat imported during the first three months after the opening of the ports, and 12s, thereafter, and other kinds of grain in proportion. In 1825 the importation of wheat from the British colonies of North America was wheat from the British colonies of North America was permitted, without reference to the price at home, on payment of a duty of 5s. a quarter. The following year a long-continued drought caused great apprehen-sions as to the harvest, and to prevent the disastrous consequences that might ensue had importation been prevented until the season was too far advanced to admit of supplies being brought from the north of Europe, his inajesty was authorized to admit 500,000 quarters of foreign wheat for home consumption. The crops of oats, peas, &c. being ascertained to be deficient, an order in council was issued on the 1st of September, admitting certain descriptions of grain for home consumption at an almost nominal duty until forty days after the first meeting of parliament, on the ground that "if the importation for home consumption ground that "if the importation for home consumption of oats and oatmeal, and of rye, peas, and beans, be not immediately permitted, there is great cause to fear that much distress may ensue to all classes of his majesty's subjects." Nothing could show more clearly the errors of the then existing system than the necessity that the government was under of thus interfering to this the property of the strength of i intention of checking this from time to time, in order to prevent the disastrous.

There can be little doubt, results that it otherwise would have produced. In

1927 Mr. Canning introduced certain resolutions into the House of Commons on this subject, the leading principles of which were, that foreign corn might be imported free of duty at all times for warehousing; and also be always admissible for home consumption on payment of certain duties, according to a graduated scale. The bill founded on these resolutions not being carried, the following year Mr. Charles Grant (afterwards Lord Glenelg) introduced a series of resolutions founded on the same principles as those of Mr. Canning; and, after a good deal of discussion, they were nmg; and, atter a good deal of discussion, they were earried, and embodied in act 9 Geo. IV. c. 60. In terms of this act, grain could be imported for home consumption at all times on payment of duties, decreasing as the price of grain advanced, and increasing as the fill. When the price of wheat was 66s and under 38 It fell. When the price of wheat was down and thuch offer, the duty was to be 20s. 3d., an additional 1s. of duty being imposed for every 1s. of decrease in the price under 60s.; between 67s. and 68s. the duty was 18s. 3d., increasing up to 73s., at and above which there was a uniform duty of is. per quarter. For barley, cats, rye, &c., there were similarly graduated scales. The prices which regulated the duties of this act were ascertained from the sales made in 150 of the principal towns of England and Wales. The dealers were bound, under a penalty for each omission, to make weekly returns of all their sales, to the corn inspectors of the different towns, who reported them to the comptroller of corn returns in London. From these reports the average weekly price of each kind of grain was computed, and the aggregate average price for the previous six weeks; and a certified copy transmitted to the collectors of customs at the different ports, and also published weekly in the Gazette. The duty on importation was regulated by the aggregate average for six weeks. In 1829 and 1830, the crops being deficient, there was a large inportation of corn, the average price of wheat being about 65s. a quarier. The crops from 1831 to 1835 being more than usually abundant, importation had almost wholly ceased, and in the last of these years the amost wholly ceased, and it are less of these years he price of wheat was as low as 39s. 4d. a quarter. In 1837 and the five following years, the crops were defi-cient; and in January, 1839, wheat was as high as 81s. a quarter. The inability of the sliding scale to maintain anything like a uniformity in the price of corn being abundantly proved, Lord John Russell, in name of the government, proposed, in 1841, the substitution of a fixed duty of 8s. a quarter on wheat, 4s. 6d. on barley, and 3s. 4d. on oats; but the ministry going out of office soon after, the proposal fell to the ground. In 1842, Sir Robert Peel introduced and carried his measure, in which the sliding scale was still retained, but largely modified. Under 51s., the duty on wheat imported from foreign countries for home consumption was 20s. decreasing gradually as the price rose to from 86s. to 69s., when the duty was 6s., and again decreasing gradually to 1s. when the price was 73s. or up-wards. The duty on colonial wheat when the price was under 55s. was 5s., and when 58s. and upwards, 1s. One hundred and thirty-eight new towns were also one nunarea and unity-eight new towns were also added to the 150 which under the former act, made returns of prices. All efforts, however, to maintain the price of corn at an equable rate were in vain, and in 1845 the unsatisfactory state of the corn harvest. and the failure of the potato crop in Ireland created serious apprehensions of a famine over the country. The Anti-Corn-Law League was also actively carrying on its operations, and monster meetings were being beid in different parts of the country, and addresses presented to the queen, praying for an abolition of the corn duties. On the 19th January, 1848, parliament was opened by the queen in person, and immediately thereafter Sir Robert Peel, who had for so many years been an active supporter of the corn duties, announced that he had been led to change duties, amounced that he had been led to change his views on the subject and to adopt the principles of free teads. On the 27th of January he detailed to the house his great scheme of commercial and Basacial solicy. It was finally arranged that that subject should be taken up by the house on the 9th of February. The debate was continued, by repeased adjournments, into the third week, when it finally terminated on the 27th of February, by a division on the twelfth night, when 337 members voted in favour of the measure and 240 against it: maiority. of the measure and 240 against it; majority, 97.

The second reading of the Corn Law bill was carried by a majority of 83, and the third reading, on the 1845 of May, by a majority of 98,—327 being for, and 229 against the measure. The debates were carried on with much acrimony on both sides, and, in particular, the personal character and motives of Sir Robert Peal were frequently and violently attacked. On the 18th of May, the bill was brought into the House of Lorde by the duke of Wellington, and after a series of animated debates and strong opposition, the bill was length carried, and received the royal saction on the 26th of June. By this act, 9 & 10 Vict. c. 22, the total repeal of the corn laws was provided for at the end of three years, or on the 1st of February, 1849; the duties being, in the mean time, considerably modified. On and after 1st February, 1849, wheat and other corn was subjected to a fixed duty of 1s. a quarter, and flour and mend of all sorts to a fixed duty of 44d. a cwt. Under the art of 9 Geo. IV. c. 60 (from 1828 to 1842), the entire quantity of foreign wheat imported was 13,562,856 quarters and 4,305,150 cwt. of foreign wheat flour, besides 597,700 quarters of colonial wheat and 1,744,591 cwt. of colonial wheat flour, besides 597,700 quarters of others and 1,745,591 cwt. of wheat and 1,804,223 cwt. of wheat and 1,004,223 cwt. of wheat meal and flour; in 1851, 3,83,638 quarters of wheat and 3,800,352 cwt. of wheat, 5,080,220 cwt. of wheat meal and flour; and 7,125,667 quarters of other kinds of corn. The gross amount of customs duty received from corn imported into the United Kingdom in 1860 was almost £1,200,000. The principal countries from which our foreign combined are Russia, Denmark and the Duchies, Prussia, France, United States, Turkey, and Egypt.—Ref. Encylopedia if McCulloch's Commercial Dictionary.

Corn Ren's a rent paid for land, varying in amount according to the price of corn. The principle is that a certain portion of the produce of the land is to be paid to the landlord for rent, not in kind, but at its money value. The quantity is fixed, but the value fluotnates with the average price of grain, which is sometimes taken for one year and sometimes for several. In many parts of Scotland rents are still paid in this way, being determined by the flars-prices which are fixed annually in each county by the sheriff and a jury. (See Fires.)

COHNACES, kor-nai-se-e, in Bot., the Cornel or Dogwood fam., a nat. ord. of dicotyledonous plants of the sub-class Casyciflora. They are trees, shrubs, or rarely herbs, with simple, exstipulate, and (with but one exception) opposite leaves. The flowers are generally perfect, but occasionally unisexual, with a superior four-lobed calyx; a corolla of four petals, with valvate æstivation; four stamens, alternate with the petals; an inferior ovary, usually two-celled, having a single pendulous anatropous ovule in each cell, and furnished with a simple style and stigma. The fruit is drupaceous. The embryo is in the axis of flesby albumen. There are nine genera and forty species natives of the temperate parts of Europe, Asia, and America. They are chiefly remarkable for tonic, febrifugal, and

astringent properties. (See CORNUS.)
CORNABINTS, kor-nar'ists, in Eccl. Hist., were the followers of one Theodore Cornhert, who flourished in the latter half of the 16th century, and was secretary of the States of Holland. He was a man of great ability, but a religious enthusiast, and wrote against the sects. He maintained that no one had any warrant to be a religious reformer who could not work miracles, and that it was not necessary for salvation to be a member of any church.

CORN-CRARE, or LANDRAIL, korn'-kraik (Gallinula craz).—The corn-crake appears to be extensively spread over the whole continent of Europe, and in Holland it is specially abundant. It is migratory, arriving here about the beginning of May. It is about the size of a partridge. All the feathers of its upper park are blackish-brown in the fliddle, edged with ash-colour; breast olive-ash; throat, belly, and abdomen white. Its habits are extremely shy. It selects for its abode grassy meadows, osier-beds, and such places, where its

566

#### Cornes

may remain completely hidden. Its food is worms, enails, and insects. The nest is composed of tender water-flags and grasses, and from eight to twelve eggs, of a yellowish white, dotted with rusty spots.

of a yellowish white, dotted with rusty spots.

CORNEA, kor-ne-ā (Lat. cornu, a horn), in Anat., is
the name given to one of the coats of the eye, from its
being of a horny consistence.

CORNEN, kor-net (Ital. cornetta, a small flag), the
designation of commissioned cavalry officers of the
lowest grade. Cornets in the cavalry rank with ensigns of infantry regiments and second lieutenants of
engineers, artillery, and marines. The cornet is so
called from currying the guidou, or small square regimental flag.

mental flag.

CORNET-A-PISTON, kor'-net-a-pis'-ton (Fr.), a new kind of wind instrument, extremely popular amongst mo-dern composers. It is in reality a post-horn with the addition of three pistons. According to Konig, the carliest idea of a piston suggested itself to a German named Herr Stolzel, who, in the year 1806, introduced one successfully into the French horn, whereby the number of its stopped tones was diminished. Shortly after, the use of a second piston was adopted, and then Cornets à deux pisions were introduced, while at the present day we have metal instruments with three and four pistons, ranging from the highest to the lowest brass instruments, each susceptible of a chromatic scale, not one sound of which is of a closed nature. best instruction-book for the cornet-a-piston is that by Komig.

CORNICE, kor'-nis (Fr. corniche), in Arch., the name of the upper part of the entablature (see ARCHITECTURE) which comes immediately above the frieze. It is

divided into two principal parts, the upper of which paris, the apper of which projects considerably be-yond the lower, being supported by modillons or mutules. The fillet, which composes the lower part, with an echinus moulding and smaller fillet above it, from which the modillous project, and an ogce, or bed-mould below it, which separates below it, which separates it from the frieze, is generally enriched with dentils, especially in the Corinthian and Composite orders. The upper part is subdivided into two portions,—the coro-

ns, which rests on the modillons, and the cynatium, which surmounts the corona. The term cornice is also applied to the ornsmental moulding projecting from the upper part of the walls of a room immediately

under the ceiling.

CORNISH CRUCIBLES. (See CRUCIBLES.)
CORNS, korns (Aug.-Sax.), are certain small, hard,
troublesome excrescences on the feet, arising from a thickening of the cuticle or epidermis, and owing generally to irritation, caused by excessive pressure or friction on the part. Corns are of two kinds,—lard and soft, the latter being situated between the toes. Frequently a bursa, or bag, is formed beneath the corn. which is apt to inflame and cause great pain and irritation. In the treatment of corns, the great object is to remove all undue pressure or friction; and for purpose, the boots or shoes should be easy and pliant. This will be still further effected by protecting the corn with a small piece of thick soft leather, spread with diachylou or other emollicut plaster, and having a hole in the centre corresponding with the size of the corn. The feet should also be frequently bathed with warm water, and as much as possible of the corn carefully pared away, care being taken not to wound the more sensitive part. If the corn is very sensitive, it ought to be occasionally touched with lunar caustic; and if much inflamed, a warm bread poultice should be applied to it.—Ref. Sir B. Brodie's Lecture on Corns and Bunions, in Medical Gazette of 13th February, 1836.

CORNUS, kor'-nus (Lat. cornu, horn, the wood being held to be duruble and hard as horn), in Bot., the typical

#### Corolla

gen. of the ast, ord, Cornaces, including several useful plants. The bark of C. forida is much esteemed in North America se a substitute for Peruvian bark is the treatment of intermittent and remittent fevera. the treatment of intermittent and remittent fevers. The fruit of C. mascula, the cornelian cherry, is astringent, and has an acid juice, which is used by the Turks for flavouring their sherbets. The seeds of C. seasoninea, the common dogwood of our hedges, yield a fixed oil, adapted for burning in lamps.

CORDY, kor'o-de (Ital. corredo, provision), is species of incorporeal hereditaments being a right of sustenance, or to receive certain allotments of victual and voyering for one's maninearnes.

and provision for one's maintenance.

COBOLLA, ko-rol'-la (Lat., a little crown), in Bot., the inner envelope of the flower, consisting of leafy organs called petals, and situated, in a complete flower, between the calyx and the stamens. It is generally the most conspicuous whorl of organs, being more or less coloured. It is, in fact, that part of the plant which usually delights us most by its gay appearance and fragrance. Petals are rarely green, though occasionally this colour is mot with, as in some Cobaas, in Hoya viridiflora, Gonolobus viridiflorus, and Penta-tropis spiralis. When there is but one whorl of entropis spiralis. When there is but one whorl of enveloping organs in the flower, it is regarded as the calyx (which see), and the flower is said to be apetaloid. A petal is often narrowed below into a staklike portion unalogous to the petiole of a leaf, as in the wallflower; the narrowed portion is then termed the unguis or claw, and the expanded portion the limb. Such a petal is said to be unguiculate or clawed. The shapes of petals are indicated in botanical descriptions by terms easily understood; such as oblong, lanceolate, elliptic, orbicular, coatc, and cordate, applied to the outlines, and concure, tubular, and bout-shaped, applied to the forms of petals which are not flat. In describing their direction, the terms erect, countent, divergent, and reflexed, are used in the same sense as when applied to the parts of the calyx. The petals, like the sepals, may be either distinct, or more or less united into one body. In the former case the corolla is said to be polypetalous or dialypetalous, in the latter, monopetalous or gamopetalous. In number of petals in a polypetalous corolla is indicated by a prefix, as in the case of a polysepalous calyx: thus a corolla of two petals is said to be dipetalous; of three, tripetalous; of four, tetrapetalous, and so on. When the petals are all of the same size and form, the corolla is termed regular; when they vary in these particulars, it is said to be irregular. We

give below the more important forms of the regular polypetalous corolla Cruciform. - This corolla gives the nat. ord. Cruciferæ its name. It consists of four petals, usually with claws, as in the wallflower (see figure, in which two of the petals show the claws), but sometimes without claws, as in the ce-

CRUCIFORM COBOLLA.

landine, and the whole arranged in the form of a cross. Caryophyllaceous, -consisting of five petals with long claws inclosed in the tube of the calyx, and with their limbs commonly placed at right angles to the claws, as in the lychnis, placed at right angles to the claws, as in the lydning, single pink, carnation, and catchify. Rosaccous,—composed of five petals, without, or with very short claws, and spreading in a regular manner, as in the strawberry and single rose. There are many anomalous forms of the irregular polypetalous corolla to which no particular names are applied. There is one form, however, of great importance, namely, the Papi-lionaccous. This derives its name from the fancied resemblance which it bears to a butterfly (papilo). It & composed of five petals, one of which is superior and larger than the others, and is termed the standard. or verillum; two are inferior, and usually more or less united, so as to form a somewhat bost-shaped cavity.

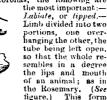

called the keel or carina; and two are lateral, and termed the wings or als. This curious form is common termed the warge or acce. Ann surrous to he various species of pea, and a vast number of plants which form the sub-ord. Papilionaces of the Leguminoes. When the petals unite, so as to form a monopetalous corolla, various terms are used; as in the case of the monosepulous culyx, to indicate the degree of adhesion; such as partile, cleft, toothed, and entire. (See Calxx.) The part where the union has taken place is called the tube; the free portion the limb; and the crifice of the tube, the throat or fuex. The monopetalous is regular when the parts are of the same size and form, and united so as to form a symmetrical body; it is irregular when these conditions are not complied with. The most noteworthy forms of the regular monopetalous corolla are distinguished

CAMPANULATE COROLLA

out, as in the central florets of many composite plants, hke the Chrysanthemum, and Ragwort, Chrysanthemum, and Miltoil. Campanulate, or bell-shaped. — Rounded at the base, and gradually enlarging to the summit; as in the Harebell. (See figure-a, stigma; b, corolla; c, calyx.) Infundibuliform, or funnel-shaped; as in Convolvulus and Tobacco. Hypocrateriform, or salner-shaped.—The tube long and narrow, and the limb at right angles to it; as in Phlox, Auricula, and Primrose. Rotate, or wheel-shaped.—Tube short, otherwise similar to the preceding

form; as in Forget-me-not. Urcsolate, or pitcher chaped .- Swollen in the middle, and contracted at both the base and spex; as in the Purple Heath. Of irregular monopetalous corollas, the following are

(See

This form

LABIATE COROLLA.

is common to most of the plants included in the nat. ord. Labiata. Personate, or masked.—Resembling the labiate in being divided into two lips; but distinguished by the lower lip being approximated to the upper, so as to close the orifice of the tube or throat. It is seen in the Snap-dragon and Toadflax. The Calceolate, or slipper form, which occurs in Calceolaria, is but a slight modification of this form. Ligulate, or strap-shaped .- A tubular corolla, partly split open on one side; as in the whole of the florets of the Dandelion, and in the florets of the ray of the Chrysanthemum and Daisy. Digitalior glove-shaped .- Somewhat bell-shaped, but alightly irregular; as in the Foxglove. The corolla, whether polypetalous or monopelalous, is subject to various irregularities, arising from the expansion or growing outwards of one or more of the petals into processes of different kinds. Thus, in the Snapdragon and Valerian, the lower part of the tube becomes di-lated on one side, so as to form a little bag, and the corolls is then termed acceute or gibbous. Sometimes a petal, or the tube of a monopetalous corolla, becomes prolonged downwards, so as to form a spur. Examples of sparred or carcarate petals or corollas may be seen in the Heartsease, Columbine, Tondflax, and Red Valerian. On the inner surface of the petals of many flowers there are curious appendages in the form of scales or hair-like proceases. Sometimes these scales proceed in state from the palace to the abbay, accompare more or less adherent, and form a cup-shaped panied by the representatives of foreign powers, both process; as in Narcissus: to this the term crown is commonly applied, and the corolla which exhibits it is said to be crowned. If the corolla falls as the flower great officers of state, and the noblemen heuring opens, as in the Grape-vine, it is caucous; if it falls the regalia, and then proceed to the royal household, proced in state from the palace to the abbay, accompanied in the same times of the sovering is received by the series of the royal household, proced in state from the palace to the abbay, accompanied in the foreign the palace to the royal household, proced in state from the palace to the royal household, proced in state from the palace to the royal household, proced in state from the palace to the royal household, proced in state from the palace to the subset, and the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the sovering at the west entrance of the abbay, the solution at the west entrance of the abbay, the solution at the west entrance of the abbay, the sovering at the west entrance of the abbay, the solution at the west entrance of the abbay, the solution at the condition at the

sistent, and then it usually becomes dry and shrivelled, as in Heaths and Campanulas, and is said to be mar-cescent. (The above remarks are abridged from Bentley's Manual of Botany, to which reference should be made by those requiring fuller information respect-

ing the various forms of the corolla.)
Corollary, kor'-ol-li-re (Lat. corollarium, properly signifying a gratuity or donation to an individual over and above his due), is usually employed to designate a necessary consequence of a proposition.—In Geom, it is a consequence drawn from some proposition already demonstrated, without the aid of any other

proposition. CONOLITELORE, ko-rol-le-flor'-e, in Bot., a sub-class of Dicotyledones, comprising those plants which have flowers furnished with both calyx and corolla, the latter being composed of united petals; the stamens are inserted on the corolla or ovary, or free and arising from the thalamus. The Corolliforæ are subdivided into-Epiquia, in which the calve is adherent, and the ovary consequently inferior; Hypostuminea, in which the stamens are inserted into the thalamus, and do not adhere to the corolla, while the ovary is superior; and Epipetalæ, or Epicorollæ, in which the corolla arises from the thalamus, and has the stamens attached to it, the ovary being superior. Fifty-eight natural orders are included by Professor Bentley in the sub-class; namely:—Subdivision 1. Epigyne.—Capritolisecæ (the Honeysuckle ord.), Columbliacew, Valerianacew, Dissacacew ord.), Columbliacew, Valerianacew, Dissacacew (the Madder) and Nothernacew, Campaigner Comments. (the Tezel ord.), Calyceraceæ, Compositæ, Campanulacer, Lobeliacer, Goodeniacers, Stylidiacers, Vacciniacer, Lobeliacers, Goodeniacers, Stylidiacers, Vacciniacers, Ericaces (the Heath ord.), Monotropicers, Pyrolacers, Epigaridacers, Subdivision 3. Epipetake.—Ebenaces (the Ebony ord.), Aquitou-aces (the Holly ord.), Sapotaces, Styracaces, Apo-cynaces, Loganiaces, Diapensiaces, Stilbaces, Gen-tianaces (the Gentiaa ord.), Asclepiadaces, Con-cessional Polymoriaces (the Phlox Convolvulacese, Cuscutacese, Polemoniacese (the Phlox ord.), Solanaces (the Potato ord.), Atropaces. (the Deadly Nightshade ord.), Oleaces (the Olive ord.), Jasminacese, Salvadoracese, Myrsinacese, Ægiseracese, Primulaceæ (the Primrose ord.), Piumbaginaceæ, Plantaginaceæ, Hydrophyllaceæ, Boraginaceæ, Ehretiacem, Nohanacea, Labiata, Verbenacea, Myoporacea, Scharianeea, Pedaliacea, Gesneracea, Crescentiacea (the Calabash-tree ord.), Bignoniacea, Acanthacea, Serophulariacea (the Fig.wort ord.), Orobanchacea, (the Broom-rape ord.), Lentibulariacem. The natural orders placed in the first subdivision were included by De Candolle in the Calycifloræ; the Corollifloræ of his system being made up of those monopetalous orders in which the corolla is hypogynous, and the ovary consequently superior. The arrangement followed in this work is preferable, as it makes the monopetalous corolls the essential mark of the Corolliflora.

CORONATION, kor-o-nai'-shun (from Lat. corona, & crown), is the act of crowning or consecrating a king. The practice is very encient, as we read in Scripture of the coronations of Solomon and of Jossh, the son of Ahaziah. Generally it has been accompanied by audinting with oil, which probably originated with the Jews. In the history of England, after the kingdoms of the heptarchy became united, the ceremony coronation is frequently alluded to; but the first English coronation of which we have any detailed account is that of Richard I. Minute accounts of many of the coronations since that time have been preserved. formulary generally followed in coronations since Edward III. is contained in the "Liber Regalis," preserved with great care in the archives of the dean and chapter of Westminster. On a coronation the great officers of state, the archbishops, bishops, peers, peeresses, and others, assemble at Westminster Abbey. The sovereign, with the princes and princesses of the blood royal, attended by the officers of the royal household,

## Coronation Oath

the royal anthem, and the speciators welcoming him with shouts of congratulation. He proceeds to a chair of state called the *Recognition Chair*, and, after the authem is concluded, the archbishop of Canterbury declares him to be the undoubted sovereign of this declares him to be the undoubted sovereign of this realm. The king next passes to the altar, and there makes the first offering; and, after returning to the chair of state, the Litany is read by two bishops, and the communion service by the archbishop, assisted by a bishop. The sermon is next preached by the archbishop of York or the bishop of London, after which the oath is administered by the archbishop of Canterbury. A hymn is then sung, and the archbishop reads a prayer, which is followed by the anthem "Zadok the priest and Nathan the prophet." The archbishop them snoints the king on the lead and hands in the form of a cross with the consecrated oil, pronouncing form of a cross with the consecrated oil, pronouncing the words, "Be thou anointed with holy," &c. The investiture then takes place, and the archbishop, having consecrated the crown with prayer, with the maying consecrated the crown with prayer, with the assistance of the other bishops, places it on the sovereign's head. The peers and peercases present all put on their coronets, the bishops their caps, and the kings of arms their crowns, amid the acclamations of the assembly, the sounding of trumpets, and the firing of crum. The henclation is then propounced after of guns. The henediction is then pronounced, after which the Te Deum is sung. The enthronization is then performed; and, by the assistance of the arch-bishop and bishops, the sovereign is placed in the royal throne, and the exhortation "Stand firm and fast," &c., pronounced. The homage is next performed; the archbishop first, for himself and the other lords spiritual, repeating the words of the homage, followed by the royal dukes, and then the senior of each rank in the peerage for his own degree. The holy sacrament is next administered, after which the final prayers are read, and the blessing pronounced. The sovereign then, after having exchanged the robe of state for the royal robe of purple velvet, returns to the palace in the

Same state as he proceeded to the abbey.

Cobonation Oath is the oath administered to a sovereign on his coronation. By it he solemnly promises and swears to govern according to the statutes established by parliament and the laws and customs of the realm; to administer law and justice in mer. y; to maintain the laws of God, the true profession of the gospel, and the Protestant reformed elegion established by law; and to preserve unto the bishops and clergy of the realm, and to the churches committed to their charge, all such rights and privileges as by law do or shall appertain to them or any of them. The oath is administered in the form of question and answer by administered in the form of question and answer by the archbishop of Canterbury; after which the sove-reign, kneeling before the altar, repeats the words, "The things which I have here before promised I will perform and keep, so help me God," and then kisses the Book. The coronation oath, and the alterations which it has undergone, are amply discussed by Mr. Taylor in his Glava, of Regality.

Taylor in his Glory of Regality.

CORONER, kor'-o-ner.—The office of coroner is a very ancient one at the common law. He is called coroner, coronator, because he has principally to do with pleas of the crown, or such wherein the sovereign is more immediately concerned; and in this light, the lord chief justice of the Queen's Bench is the principal coner justice of the queen's Bench is the principal coroner of the kingdom, and may, if he pleases, exercise the jurisdiction of a coroner in any part of the realm. But there are also particular coroners for every county in England, usually four, but sometimes six, and sometimes fower; and in every borough having separate quarter sessions, a coroner is appointed, with exclusive jurisdiction within the borough. This officer is of equal antiquity with the sheriff, and was ordained with him to keep the peace when the earls gave up the wardship of the county. He is chosen by all the free-holders in the accient county court; but the crown and certain lords of franchises, having a charter from the crown for that purpose, may appoint coroners for certain precincts or liberties by their own mere grant, and without election. He is chosen for life, but may and without election. He is chosen for life, but may be removed by being made sheriff, which is an office incompatible with the other, or by the writ de coronatore exonerando, on account of engagements in other business, incapacity by years or sickness, or for that he has not a sufficient estate (lands to the amount of

## Corporation

twenty pounds per annum) in the county, or lives in an inconvenient part of it, or is guilty of extortion, negled, or mistelawiour. He may appoint a deputy by writing under his hand and seal. His duties are udicial or ministerial; but his principal duty is to inquire, when any person is slain, or dies suddenly or in prison, or under suspicious circumstances, concerning the manner of his death. He is also to inquire concerning shipwrecks, and certify whether wreck or not, and who is in possession of the goods. Concerning treasure-troop, he is also to inquire who were the finders, and where it is, and whether any one be suspected of having found and concealed a treasure. He is a conservator of the queen's peace, and becomes a magistrate by virtue of his appointment, having power to cause felons to be apprehended, whether an inquisition have been found against them or not. His ministerial office (as the sheriff's substitute) is to exeministerial office has the sheriff sausstatue) as to exe-cute process in cases where the sheriff may be sus-pected of partiality, as that he is interested in the suit, or of kindred to either the plaintiff or defendant.— Ref. Jervis On the Office and Duties of Coroners.

COBONET, kor'-o-net (Lat. corona, a crown), an inferior kind of crown worn by princes and noblemen as distinctive tokens of their several degrees. They will be found illustrated and described under CBOWN

CORPORAL, kor'-por al (Fr. caporal, Ital. capo, head), in Mil., the designation of a non-commissioned officer who ranks next to a sergeant, and immediately above a lance corporal. It is the duty of the corporal to reliere and place sentries. When the regiment is on parade, he falls into the ranks with the privates. The corporal receives a somewhat higher pay than a private, and is distinguished by wearing two chevrous on. his arm. (See CHEVRONS.)

CORPORAL (Lat. corpus, a body) is the name given to the linen cloth which is spread over the consecrated bread (corpus, or body) after the communion. In the Romish and Greek churches it is an object of great reverence, and the folding and unfolding of it by the priest at the altar is accompanied with much ceremony, It is said to represent the wrapping of the body of our Lord in fine linen by Joseph of Arimathea. The cor-poral oath is derived from the ancient usage of touch ing the corporal to add solemnity to an oath.

CORPORAT PUNISHMENT. (See Flogging.)
CORPORATION, kor-por-uv-shan (Lat.), is a body
politic or incorporate, so called as the persons are
made into a body, and of espacity to take and grant, &c.; or it is an assembly and joining together of many into one fellowship and brotherhood, whereof one is flead and chief and the restare the body, and this bead and body kuit together make the corporation; also it is constituted of several members, like unto the natural body, and framed by tiction of law to endure in perpetual succession. Of corporations, some are sole, some aggregate: sole, when in one single person, as the queen, a bishop, dean, parson, vicar, or the like; aggregate, which is most usual, consisting of many persons, as mayor and commonalty, dean and chapter, &c. Likewise corporations are spiritual or temporal: spiritual, as bishops, deans, archdeacons, parsons, vicars, and other ecclesiastical persons; temporal, as mayors, commonalty, bailiffs, and burgesses, &c., of towns and boroughs; and some corporations are of a mixed nature, composed of spiritual and temporal persons, such as heads and fellows of colleges and hospitals, &c. Lay corporations are of two sorts,—civil and eleemosynary. The civil are such as are erected and elemosynary. The civil are such as are erected for a variety of temporal purposes, as the king or queen, to prevent the possibility of an interreguam or vacancy to the throne, and to preserve the possessions the built built built. of the crown entire; a mayor or commonalty, bailif, and burgesses, or the like, for the good government of a town; others for the advancement and regulation of commerce, as the trading companies of London and other towns, and public companies instituted by act of parliament or royal charter, and others for the better carrying on of divers special purposes, as the colleges of Physicians and Surgeons, the Royal Society, the Society of Antiquaries, &c. Among these the general corporate bodies of Cambridge and Oxford must be

ranked, which are not strictly spiritual or ecclesiastical, being composed of more laymen than clergy; neither are they eleemosynary foundations, though stipends

are sunexed to particular magistrates and professors, and these stipends are preceded by service and duty. 

\*\*Riemosynary are such as are constituted for the perpetual distribution of the free alms or bounty of the founder to such persons as he has directed or as the mode of government has been defined. Of this kind are all hospitals for the maintenance of the poor, sick, and important and all colleges both in our prisonicity. are all nospitals for the maintenance of the poor, sice, and impotent, and all colleges, both in our universities and out of them. Corporations, both sole and aggregate, may purchase, take, and hold land to them and their successors, as natural persons may hold them and their sire; but they are subject to the provisions of the law as to devises to charitable uses and the statutes of mortmain, and must have a license from the crown to enable them to hold or alien their lauds in mortmain; but aggregate corporations, when of the corporations sole, are in general restrained by statute from alienation of their lands, beyond the life of the person who constitutes the corporation sole or is the ead of the corporation aggregate. Power is nevertheless given to them, in some cases, to grant long building leases. Corporations aggregate may sue and be sued, and do all other acts, by their corporate name. Their corporate property only, and not the members individually, is amenable to judgments given against them. Their acts are under their common seal. There are some personal acts, however, as to which convenience has introduced an exception to this rule. Thus to a bailiff to make a distress. It may make by-laws or private statutes for the better government of the corporation, not contrary to the laws of the land, or contrary to or inconsistent with its charter, or manifestly unreasonable. It must appear by attorney, for it cannot in person. It cannot maintain or be made it cannot in person. defendant to an action of battery or the like; but it may maintain an action for breach of contract, and, in some cases, may be sued in such action as defendant. It is also liable to an action for damages in respect of any tortious acts committed by its agents, and is even liable in certain cases to an indictment, as where it allows a bridge, the repair of which belongs to it by law, to fall into decay; but in general it can be guilty of no crime in its corporate capacity. It may or no crime in its corporate capacity. It may also, under certain circumstances, be the subject of bankruptcy; as in the cases of joint-stock, banking, and other companies, founded by statute or charter for trade or profit. Aggregate corporations that have by their constitution a head, can do no acts during the vacancy of the headship, except only appointing another. There may be a corporation aggregate constituted without a head, as the collegiate church of Southwell, in Nottinghamshire, which consists only of Southwell, in Nothinghamshire, which consists only of prebendaries, and the governors of the Charterhouse, London, who have no president or superior, but are all of equal authority. The act of the major part is esteemed the act of the whole. No chattel interest can go to a corporation sole. There are several subjects relating to corporations which cannot, for want forward when heart such as a the mode of of space, be entered upon here; such as the mode of creating them; some other powers and capacities not before noticed; the mode by which they are visited for the inquiry into and correction of abuses; and the method of dissolving them. For the consideration of these, the student is referred to elementary treatises on the subject. (See MUNICIPAL CORPORATIONS.)

CORPOBATION, ACTS OF. (See TEST AND COMPORA-

TION ACT .) CORPS, ker (Ir. corps, Lat. corpus, a body), the name given in Mil. to any body of troops, without reference to the number of men of which it is composed. It can be applied with equal propriety to a regiment or battalion, consisting of many companies, or to a single company, as in the case of volunteer compa, when the company is isolated, and known by a distinctive number and title.

Cours n'Amnis, kor-dar-may (Fr.), a term applied to the large sections into which the military forces of Europe are divided in a time of peace. The British army is not large enough to be divided into corps, but in many continental states the military strength is m many commences neares the mintary excentives to be elected from the scholars, and the scholars from divided into a number of corps, each complete in itself natives of certain specified dioceses and countries. By as a sum of the present statutes, which have been recently amended, service. Every corps d'armé is subdivided into four it is provided that both follows and scholars shall be

corps, belonging respectively to the cavalry, infantry, artillery, and engineers. Among the French, 100,000 men, being considered too many to form one army, are divided into two or more corps d'armée. In the Russian system, the military strength is divided into about twelve corps, which are stationed in different districts throughout the empire. The Austrian forces are also divided in a similar manner.

CORPULENCE, kor'-pu-lens (Lut. corpulentia, fro corpus, the body), is an undue bulkiness or size of the body, arising from an excessive accumulation of fat in certain parts. It is impossible to define exactly the limit beyond which the body can be said to be corpulent, depending, as it does, very much upon the general habit and the state of health of the individual. It most commonly takes place after the age of forty, but is not confined to any particular period of life, being to be found also in childhood and youth. The causes of corpulence are both natural and acquired. There are some persons who have a natural tendency to corpu-lence; in others it may be induced by modes of life, indolent and sedentary habits, and the use of certain kinds of food. The undue accumulation of fat produces a variety of effects, interfering with the vital energies of the body, and incapneitating for exaction. The chances of life are not so great among persons of a corpulent habit as among those of a normal condi-tion. All sudden or violent measures to get rid of corpulence are attended with harm; and not the least daugerous is the popular remedy of vinegar, which has the effect of destroying the digestive powers. Attention to diet, and the avoidance of such articles as tend to generate fat, together with active exercise and the counteracting of indolent habits, are among the best means that can be employed. Dr. Chalmers, in his small treatise "On Corpulence," gives a variety of cases in which liquor potasses was used with great effect; but this remedy should not be resorted to without the sanction of a medical advisor. There are numerous very remarkable cases of corpulence on record. Of modern instances known in this country, was Bright of Maldon, in Essex, a respectable tallow-chandler and grocer, who died the 12th of November, 1750, in the twenty-ninth year of his age. He weighed 616 lbs. : and it is said that seven persons of ordinary size could be inclosed in his waistcoat. Daniel Lambert, who is supposed to have been the heaviest man that ever lived, died at Stamford, in Lincolnshire, at the age of forty, on the 21st June, 1809. He is said to have weighed 52 stone 12 lbs.. or 740 lbs.

weighed 52 stone 12 lbs. or 120 lbs.
CORPUS, kor'-pus (Lat., body), is a term applied in Anat. to certain rarts of the animal structure; as the corpus callosam, the corpora quadrigemina. It is also applied to a collection or body of laws or canons:

as Corpus juris civilis, Corpus juris canonici.
Corpus Curisti (Lat., body of Christ), is the name of a festival of the Church of Rome, instituted by Pope Urban IV. in 1264, in honour of the consecrated host, and with a view to its adoration. It is observed on the Thursday of the week after Pentecost, and is kept as one of the greatest festivals of the Roman Catholic church.

CORPUS CHRISTI COLLEGE, CAMBRIDGE, was founded in 1352 by two societies, or guilds, in Cambridge, called the guild of Corpus Christi and the guild of the Virgin Mary; and at first the college bore both names. Afterwards it acquired the name of Bene't College (by which it is still often distinguished), from the adjoining church of St. Benedict. It has twelve followships,—eight open to all the queen's subjects, wherever born; two are appropriated to natives of Norfolk, and two to the Norwich scholars on Archbishop Parker's foundation. All the fellows are required to take holy orders within three years after their election, and the degree of B.D. within eight years after that of M.A. There are also a large number of scholarships and exhibitions connected with this college, some of them being of connected with this college. siderable value.

CORPUS CHRISTI COLLEGE, OXFORD, was founded in 1516 by Richard Fox, bishop of Winchester, for a pre-sident, twenty fellows, and twenty scholars, the fellows to be elected from the scholars, and the echolars from

570

Buch

# Correction, House of

elected without any restriction as to place of birth. The scholarships are tenable for five years from matri-oulation, and are of the annual value of £80, together with rooms rent free. There are aso four exhibitions of the same value, and tenable for the same period as the scholarship.—Ref. Oxford University Calendar, 1871.

CORRECTION, HOUSE OF. (See PRISONS.) CORRELATION OF THE PHYSICAL FORCES, kor-rel-Lorentz (Lat. con, with; relatio, a throwing back), the reciprocal relation between gravitation, the molecular forces, heat and light, electricity, and animal force. (See FORCE.)

CORRIDGE, kor'-r-d-or (Mal. coridore), a long passage or college in a managion, or any large huilding, which

or gallery in a mansion, or any large building, which dependent, and have no other means of communication with each other. A corridor may be closed, or open to the air on one side.

CORROSION, kor-ro'-zhun (Lat. con, and rodo, I gnaw), the gradual eating or wearing away of any substance, such as a metal, under the action of acids, by means of which its nature is completely changed by slow

CORROSIVE SUBLIMATE, in Chem., bichloride of mer-

oury. (See Mercury, Bighloride of.)
Corsair, kor-saire' (Ital. corso, a race), a term applied generally to sea-robbers or pirates, but originally used to designate those pirates in the south of Europe who sailed from Algiers, Tunis, Tripoli, and the ports of Morocco. They were directed by their princes to attack the merchant-vessels of nations with whom they were at war.

CORSET, kor'-set (Fr.), a tight-fitting under-dress or stay for the body, worn by females. It generally consists of cloth, and is stiffened by whalebone or other means, and tightened by a lace.

CORBICAN MOSS. (See GRACILARIA.)
CORSLET, kors'-let (Fr.), a light body-armour, worn
by the pikemen about the middle of the 17th century. Sometimes the term is employed to designate the entire suit under the title of a corslet, complete or furnished, which included the headpiece or gorget, as well as the tasses which covered the thighs.

CORSNED, Or MORSEL OF EXECUATION, kors'-ned (Sax. corsnede, a compound of cors, curse, and sned, a piece or mouthful), was a form of trial or purgation made use of anciently in England. A morsel of bread was consecrated by exorcism, and was administered to a suspected person as a test of his innocence. If the person was guilty, it was held that the bread would remain in the stomach and produce pallor and convul-sions; if the person was innocent, the bread would act s a wholesome and nutritious morsel. Some state that the holy sacrament was given to the suspected person with the coraned, while others believe that the latter was nothing else than the sacramental bread itself. It is related in the old English chronicles, that Goodwin, earl of Kent, during the reign of Edward the Confessor, after declaring himself innocent of the death of the king's brother, took the corsned, which, sticking in his throat, killed him,

CORTES, kor'-tez (Sp.), is the name given in Spain and Portugal to the assembly of representatives of the nation. These assemblies have been variously constituted, and possessed of various powers, at different times in these countries. They have existed from an early period, but their origin is involved in obscurity. In Spain, on the decline of the Moorish power, as district after district was recovered by the Christian princes, we find certain political corporations rising up and limiting the power of the princes. In the two principal states (formed by the union of a number of smaller ones), Castile and Aragon, the three estamentos, or states of the clergy, nobility, and inhabitants of enfranstates of the etergy, nomery, and inheotrants of entran-chised towns, were represented in the Cortes. In Aragon the Cortes appointed a judge, who decided all questions and disputes between the king and his sub-jects, and confined the royal power within constitu-tional limits. In Castlie the rights of the states were less marked, and in particular the privileges of the burgher class, were less extensive than in Aragon. In both countries, however, the king was dependent on the Cortes. After the union of the two kingdoms, Ferdinard and Isabella succeeded in making themselves

# Corymb

independent of the Cortes; and afterwards, when the Castilians attempted to oppose an extraordinary text, at a meeting convoked at Toledo by Cherles I. in 1538, the king abolished this assembly of the states. After this neither the clergy nor nobility were assembled, but deputies from eighteen of the cities were sometimes convened, only, however, when subsidies were to be granted. The special privileges of the Aragon Cortes were much shridged by Philip II, in 1591; and after the Spanish war of succession, Philip V. deprived those provinces which had adhered to the Austrian party of the privileges that still remained to them. party of the privileges that still remained to them. From that time the Cortes were only convened to pay homage to the king or the prince of Asturias, or when nomage to the king or the prince of asturias, or men a question respecting the succession to the throne was to be determined. After 1713 they did not meet till 1789, on the accession of Charles IV. In 1809 the Cortes were assembled by the Junta, and in 1812 gave out a new constitution. This extraordinary Cortes was succeeded by the the ordinary Cortes alorted according to were assembled by the extraordinary Cortes was succeeded by the ordinary Cortes, elected according to the new constitution, in 1813; but it was dissolved by Ferdinand, on his return in 1814, and the new constitution abrogated. Numerous changes in the constitution abrogated. Numerous changes in the constitution abrogated. ferdinand, on the tution abrogated. Numerous changes in the pulse, which our tution and Cortes have since taken place, which our tution and Cortes have since taken place, which our tution and cortes have since taken place, which our tution are from entering upon. Since 1848 they have been accustomed to meet and debate; but being possessed of little power, they have generally been employed to give weight to one or other of the contending factions. The history of the Cortes of Portugal is nearly the same as those of Spain.

CORUNDUM, ker-un'-dum, in Min., a nineral containing pure alamina, and occurring in hexagonal prisms of great hardness. When coloured and transparent, corundum constitutes sapphire, and the gran-

ular variety is known as emery.

Converre, kor-vet' (Fr.), in Mar., a sloop of war, an advice-boat, having fewer than twenty guns.

Corvus. (See Cnow.)

CORYLACER. OF CUPULIFERE, kor-il-at'-se-e (Gr. korus, a lelmer, the calyx enwrapping the fruit).

Bot., the Oak fam., a nat. ord. of dicotyledonous plants, in the sub-class Monochlamydee. Trees or shrubs, with alternate leaves, usually feather-veined and simple, with deciduous stipules. The flowers are monocious, the male being clustered or in amenta, with from five to twenty stamens into the base of a membranous relivate calvy, or of scales, the female membranous valvate calyx, or of scales; the female solitary or clustered, surrounded by an involucre of bracts, which ultimately form a cupule round the every, which has three or more cells. The fruit is a glaus or nut. The plants of this order abound in the forests of temperate regions, and a few occur in the high lands of tropical climates. They are of great importance as timber-trees: many yield edible seeds, and some have astringent barks and cupules. There are about 280 known species, which have been arranged into 10 genera, the most noteworthy being Querens (the Oak), Corvlus (the Hazel), Fagus (the Beech), Castanea (the

Chestnut), and Carpinus (the Hornbeam).
CORYLUS, kor'-e-lus (Gr. korus, a helmet), in Bot., the typical gen. of the nat. ord. Corylaces, which includes the common hazel (C. acellana), a shrub well known as the original source of many kinds of edible The wild hazel of our woods yields the nuts which are gathered with so much pleasure by schoolboys; and varieties of the same species produce the different kinds known as the White, Red, and Jerusalem filberts, the Great and Clustered cobs, the Red Smyrna, the Black Spanish, and the Barcelons nuts. The importation of nuts into this country is on an average 150,000 bushels a year. The cil obtained from them by expression is occasionally employed by artists and watchmakers. From the branches of the hazel good charcoal is prepared. CORYMS, kort-imb (Lat. corymbus), in Bot., the name given to a particular form of inflorescence. It is a kind of raceme (which see), in which the peduncles

kind of raceme (which sed), in which the pedundess (flower-stalks) become gradually shorter as they approach the top, so that all the flowers are about on a level. It occurs in some species of Cerusus, in the hawthorn, and many familiar plants. When the stalks or secondary axes of a corymb, instead of bearing flowers immediately, divide and form tertiary axes, a compound corymb is produced, as in some species of

## Corymbifere

CONVENTIFIER, ker-im-bif-er-s (Let, corymbus, and fero, I bear), in Bot, the name given by Jussieu to a sub-ord. of the Composite, which consisted of plants having florets all twhlar and perfect, or having tubular and perfect florets in the disk, and tubular and pistiliferous, or ligulate, florets in the ray. The genus Chrystuthemum may be taken as an example. Two species of this genus grow wild in Britain; namely C. leucanthemum (the ox-eye) and C. segetum (the corn marigold). In our gardens a number of beautiful varieties of the species C. indicum, sincuse, and others, are cultivated. They are hardy plants, and are remarkvarieties of the species C. macum, americ, and others, are cultivated. They are hardy plants, and are remarkable for the number and the varied colours of their flowers, which appear late in the autumn. There is a fine show of blooming chrysanthemums in the gardens of the Inner Temple. London. every season.

of the Inner Temple, London, every season.

Correa, kor-i'-fi (Gr. koruphe, the summit, the leaves growing only on the top), in Bot., a gen. of palms. It includes one remarkable species, namely C. imbraculifera, the talipot palm of Ceylon, from which leaves quantities of sure are obtained.

which large quantities of sago are obtained.

COSMETIC, kos-met'-ik (Gr. kosmeo, I adorn), is a preparation used to whiten or soften the skin, or otherwise to beautify and improve it. With the ancient

Romans, the term cosmeta was applied to those slaves who were employed to dress and adorn their mistresses. Cosmogonr, kos.mog'o.ne (Gr. kosmos, the universe; gone, generation), the science which relates to the formation of the universe, as distinguished from cosmography, which treats of the universe as we see it, and from cosmology, which treats of the actual and permanent state of the carth as it is. Cosmography has been embodied as a science by Baron Humboldt, in his celebrated work entitled "Cosmos." All cosmogonists may be divided into two great classes,those who believe that the world sprang into existence at the order of the Almighty, and those who hold that the universe is in itself the body and being of Deity, and, assuch, has been in existence through all eternity. The former are termed Theistical cosmogonists, and the latter Pantheistical.

COSMOPOLITAN, kos.mo-pol'-i-tãn (Gr. kosmos, world; polites, citizen), a citizen of the world; a person who makes himself at home wherever he goes, who has no fixed residence, and is nowhere a stranger and an alien.

COSMORAMA, kos-mo-rā'-mā (Gr. kosmos, the world, and horasin, to see), an exhibition in which various scenes illustrative of remarkable events and different parts of the world are shown. The effect of the pictures is beightened by throwing artificial light upon them; and they are viewed through lenses of great magnifying power, which makes them appear to be wonderfully natural and life-like.

COSMOS. (See Cosmogony.)

Cossus, kos'-sus, a gen. of night-flying moths, having the following characteristics :- Antenne long, rather slender, furnished on the inner edge with a series of transverse elevated ridges, which resemble the teeth of a saw; two distinct palpi, thickly clothed with scales, and each three-jointed; head small, upper wings longor and larger than the lower; body large. (See GOAT-MOTH.)

Cosrs, kosts (Germ. Dan. kost), are the charges to which a person is subject in a legal proceeding, and are a necessary appendage to judgments, but are payable in various interlocutory and other proceedings. The first statute which gave costs eo nomine to the plaintiff, was the statute of Gloucester, 6 Edw. I. e. 1, as did the statute of Marlbridge, 52 Hen. III. c. 6, to the defendant in one particular case relative to wardship in chivalry, though, in reality, costs were always considered and included in the quantum of damages in such actions where damages are given; and even now costs for the plaintiff are always entered on the roll as increase of damages by the court. With the exception which has been mentioned, no costs were allowed to the defendant in any case till the sta-tute 23 Hen. VIII. c. 15, since which divers statutes have tupe 23 Hen. VIII. c. 15, since which divers statutes have been passed, both as regards plaintiff and defendant, and rules and orders of the courts have been made re-specting them. Paupers, that is, such as will swear hemselves not worth five pounds in the world, except their wearing apparel and the matter in question in the cause, are exempt, when plaintiffs, from the pay- the cotton-plant was extensively cultivated, and it

#### Cotton Manufacture

ment of court fees, and entitled to have connecl at attorney assigned to them by the court without fe and are excused from paying costs when unsuccessfu but shall suffer other punishment, at the discretion the judges. In modern practice, no instance, however of the award of any punishment in such cases has o curred; but a person thus suing in forma pauper may recover costs though he pays none for the counse and clerks are bound to give their labour to him, by not to his antagonists. And if a plaintiff shall bring a action of covenant, debt, detinue, or assumpsit in heing for breach of named at the contract of the c being for breach of promise of marriage), and he sha not recover more than twenty pounds; or, in an actio of trover or case, and he shall not recover more tha five pounds, provided any such action is cognizable i a county court, unless the judgment be by default, c unless it be certified by the judge who tries the cause or it appears to the court itself that there was suff or it appears to the court itself that there was sufficient reason for bringing the action there. To the general rule, however, there are certain exceptions as where the plaintiff dwells more than twent miles from the defendant, or where the cause cation did not arise wholly, or in some materia point, within the jurisdiction of the county cour within which the defendant dwells or carries on he lustiness at the time of the action being appearance. business at the time of the action being commenced. c (in general) where an officer of the county court is party. In cases between party and party, the cost are taxed by an officer of the court, who reduces o increases any of the charges, according to a certain scale governed or fixed by rules of the court, or at his discretion where the item is not included in such scale and, as between an attorney or solicitor and his client either party may have the costs taxed. (See ATTORNEY.

COSTUME, kos-tume' (Fr.), the term ordinarily at plied to the garments, robes, &c., of a people; thu the kilt, plaid, and hose of the mountaineers of Scot land are termed the Highland costume. The seve ral peculiarities in the dresses of doctors, masters of arts, bachelors, and undergraduates, constitute wha is generally called the costume of the university, o scademical costume. — A rule or precept in Paint ing, by which the artist is enjoined to make every per son and thing depicted sustain its proper character and not only observe the story, but that the circum stances, the scene of action, the country or place, th habits, arms, manners, &c., exactly correspond.

Coterie, ko-ter-e' (Fr.). a friendly or select party

a club or association limited to a small number c individuals. The word is of French origin, and is sur posed to have been derived from the Latin quot, ho many. In the 13th or 14th century, when merchant joined together in an enterprise, they formed a coteric and each subscribed his quota. It soon lost this signification, and now only refers to exclusive societies.

COTLING, ko-lil-yan (Fr., an under petticont), brisk French dance executed by eight persons. It was very popular in France at the conclusion of the las century, but was superseded by the quadrille, which i

itself a modified form of the cotilion.

Corrage, kol-tij (Ang. Sax.), a small habitation detached from other buildings, and generally one storhigh. The name was originally applied only to dwelling of a very humble kind, but it is now used to designate a great variety of buildings, from the ornamental cot tages of the French to the Swiss chalets. The rara cottages of England are fained as being the most beau tiful; they are generally clean and neat in the interior and picturesque and ornamental outside. A great dea of attention has been given of late years to the accom modation of agricultural cottages.

COTTON. (See GOSSTPIUM.)
COTTON, GEN. (See PYROXYLIN.)
COTTON MANUFACTURE, keit-in (Fr. coton, Ital
cotione, probably from the Arab. ketun, fine).—Thi
branch of industry, which was known in India am
China many centuries before it was introduced int Europe, is now one of the most important manufactures of Great Britain. Herodotus is the first of the Greek writers who mentions cotton: he calls it tree wool. Both the Greeks and Romans imported their cotton from India. At the present day the inhabitant of China are principally clothed in dresses made o native cotton woven at home. About the 10th century

A A

# Cotton Manufacture

produce woven into cloth by the Moors in Spain, where the manufacture flourished for some time, especially at Barcelona. The cloths made were of coarse texture, and a large quantity was used for sail-cloth. On account of the prejudice against the Moorish population, the traffic in manufactured cotton was only carried on with africa and the East. In Italy cotton fabrica began to be made about the same period. From that country the manufacture passed into the Netherlands, and was brought into England by Protestant refugees after the capture of Antwerp by the duke of Parma in As early as 1641 Manchester began to be noted as a town where cotton was manufactured. Before as a town where cotton was manufacture. Before the invention of Arkwright, the cotton manufacture in England was of very slight importance. Arkwright's patent for spinning by rollers was taken out in 1769. Previous to that year the weavers, dispersed in cottages scattered throughout the district, purchased the cotton with which they worked. Having supply is and wown it scattered throughout the district, purchased the cotton with which they worked. Having spun it and woren it into cloths, they took their goods to market, and sold them on their own account. The rapid growth and prodigious magnitude of the cotton-manufacture of Great Britain form one of the most extraordinary phenomenants with history of industry. In 1200 the March nomena in the history of industry. In 1760 the Man-chester merchants began the system of distributing the supplies of cotton wool among the weavers by means of agents. A few years afterwards, Hargreave, an ingenious but illiterate weaver, invented the spin ning-jenny,- a machine by which eight threads could be spun at a time, against one by the distaff or spinning wheel. This invention was much opposed by the working weavers in the district. They destroyed his working weavers in the district. They destroyed his machine, and compelled him to leave his native place. A few years afterwards, Richard (afterwards Sir Richard) Arkwright, a hardresser, brought out his machine for spinning by rollers. The principle of the patents taken out by Hargreave and Arkwright were combined by Mr. Committen, who should be former. combined by Mr. Crompton, who shortly afterwards invented a piece of mechanism called the mule-jeung. It produced a much finer yearn than either of the other machines. Crompton received a grant of £5,000 from the government for his service. At first the mule-jenuics consisted of not more than thirty spindles each; now they frequently contain 1,000 to 2,000 spin-dles, with which threads have been produced 1,000 miles long, and only one pound in weight. The first steam-engine for a cotton-mill was constructed by Mr. Watt in 1785. At this time the application of the improved machinery was confined to the production of yarn; and as the difficulty had formerly been to find thread enough to supply the looms, so now it seems to have been feared that it would be impossible to find a sufficient number of weavers to work the thread that was spun. Dr. Cartwright, however, supplied this great desideratum by his invention of the power-loom. invention was followed by the cylinder printing-machine, mechanical engracing, and the processes of calico-printing and bleaching. (See Calico-puinting and bleaching. (See Calico-puinting has been further facilitated by the self-acting mule of Messrs, Sharp, Roberts, & Co., of Manchester. These machines do not require the named of a contraction. but can be attended to by a boy or girl, whose duty it is to join the threads which break during the spinning. A great variety of apparatus and a large number of machines have been invented of late years; but, for the most part, they consist of extensions or improvements of the inventions of Hargreave, Arkwright, Crompton, Cartwright, and Roberts. The ordinary process of cotton manufacture is as follows:—The raw material, when it arrives at the cotton-mill, is first taken to the mixing-room. The contents of each bug are spread out in a horizontal layer of uniform thickmess, the contents of the several bags forming separate

# Cough

cotton is then passed through the spreading machine, and afterwards wound in a fleecy state upon a large wooden roller. In this state it is conveyed to the carding machine, where it is drawn out into parallel layers. (See Carding-Mackins.) Each of these layers is made to undergo compression in its way to a willow from which it is introduced. roller, from which it is given off in the form of a thick. soft thread, into a tin can. This thread is called a sliver. The next stage is termed drawing, and the machine employed is called a drawing-frame. The sliver is passed through the drawing-frame, which completes the process begun by the carding-machine, the fibres of the cotton being arranged longitudinally in a uniform and parallel direction. This drawing opera-tion is repeated several times, in order to correct all inequalities. The next process is rowing,—a continua-tion of the drawing. The cord, which is now called a rove, being much thinner, has a slight twist given to it by passing through a can, which is made to revolve with great velocity while receiving it. It is then wound upon hobbins, and is ready for the spinning-frame. As the spinning and weaving of cotton differ very slightly from that of silk, linen, woollen, &c., they will be found described under the articles SPINNING and WEAVING. Sea-Island and long-stapled Egyptian cotton are the varieties from which the finer kinds of yarn are spun; and from them muslins, laces, &c., are made. Cambrics, shirtings, calicoes, &c., are made from Brazilian and the better classes of American cotton. Coarse yarns, used for making fustians and other heavy fabrics, are made from the inferior quali-ties of America and Surat. From wefts of wool or worsted and warps of cotton several varieties of Coburg and Orleans cloths, mousselines de laine, damasks, &c., are made. The Yorkshire broadcloths are sometimes one-half cotton. Fabrics are also made of linen and cotton, silk and cotton, &c. The continent of Europe was formerly the largest consumer of yarn made in England, but now the principal demand comes from India and Chius.

COTTUS, kot'-tus (Gr. kotta, a head), the name of a gen, of spiny-finned fishes, characterized by the large Size of the head; whence their name. There are two species of this genus to be found in British seas,—the sea Scorpion (Cottus Scorpio) and the Father-lasher (Cottus bubalis).

COTYLEDON, ko-til-e'-don (Gr. kotule, a cavity, in allusion to the cup-like leaves), in Bot., a rudimentary leaf, forming part of the embryo of a flowering plant. (See EMBRYO.)

COTYLEDON, in Bot., the Navelwort, a gen. of plants belonging to the nat. ord. Crassulaceæ. The species C. umbilicus is a common plant on walls and rocks in the West of England. It has long been in use as a popular remedy in hysteria, and as an external application to destroy corns and warts. Of late years it has been frequently employed as a remedy for

COTYLEDONES, ko-til-e-do'-nees, in Bot., a name sometimes applied to the sub-kingdom Phanerogamic

or flowering plants. (See systematic arrangement of plants in the article BOTANX.)

COUCAL (Egyptian), koo'-kül (Centropus couptus), a bird about filteen inches long. The feathers of the head and neck are of a metallic greenish hue, which colour, passing to a duller tint, marks the bird's upper parts generally, while the under portions are white. They are solitary in their habits, breeding in holes in trees, and feeding on insects and small reptiles. Its note somewhat resembles that of our cuckoo; indeed, the Arabs call the bird hou-hou, from its repetition of these syllables.

COUGH, kof (qu. Du. kuch), is a spasmodic action of the respiratory organs, occasioning a violent and sonorous expulsion of air from the lungs. Coughing ness, the contents of the several bags forming separate layers. The heap is then trampled or pressed together. The cotton of which this bing, as it is called, is composed is then torn down by a rake from top to bottom, and a portion of each layer thus obtained. If the layers consist of different qualities of cotton, a uniform mixture is thus obtained. The quantity raked down is then conveyed to the veucleing or willowing machine, where it is dragged through two rollers, transferred to two beaters, which thrash out all sand, seeds, and traches, and bronchi are endowed with a very high other mixture is thus obtained. The quantity raked down is a layer so that the sir-passages to the lungs should be perfectly free from any obstruction; and hence the larynz, two beaters, which thrash out all sand, seeds, and traches, and bronchi are endowed with a very high other rollers and a second set of beaters. The cleansed foreign body causes the most violent excitement.

#### Coumerin

Conghing, then, is occasioned by an irritact in these parts, and is an attempt to get rid of the irritation. The air from the lungs is suddenly driven up with great force through the air-passages, so as to carry with it any causes of irritation that may be present in them. Cough may also be excited by irritant vapours or gases, or may arise from an abnormal sensibility of the lining membrane. In most cases cough is attended with expectoration, but sometimes it is quite dry. When the mucous membrane of the air-passages is unduly stimulated, the vessels become overloaded with mucas, and coughing is produced to effect its discharge, as is frequently observed in catarrh. This kind of cough is often a chronic disease in old age, and is frequently very troublesome. The dry cough, which is mostly unattended by any expectoration, is obviously of a nervous character, and is observed in highly irritable, nervous, and hysterical constitutions. The treatment of cough, when symptomatic of any other disease, will be found noticed in other parts of this work; as Caranen, Brokeniris, Pirmusis. When it is occas oned by the irritation of the mucus, it is to be treated with demulecut; as mucilaginous drinks and liquorice. Stimulants and full diet are to be avoided, and inflammatory symptoma carefully guarded against. Sedatives, expectorants, and aperients are often very useful in effecting a cure. Great relief is frequently afforded by the use of the warm foot-bath and warm gruel, with a ten-grain Dover's powder after the patient is in bed, and then plenty of covering to encourage perspiration. In dry coughs should never be neglected; for they are frequently symptomatic of organic disease, or may induce it. If they do not yield to simple remedies, medical

definity symptometro to game traces, of many induces.

1. If they do not yield to simple remedies, medical advice ought to be sought.

Counsily, koo'-mārin, in Chem., C<sub>18</sub>H<sub>2</sub>O<sub>4</sub>, an odoriferous crystalline principle, found largely in the Tonka or Tonquin bean (see Dipperxxx), the common realists and in the process remediate versus of the process vernal grass. in the sweet-scented It is to this odoriferous principle that the pleasant scent of new-mown hay is due; and by combining the essential oil of Tonka-beans with other scents, perfumers are accustomed to imitate with great accuracy the odour of a field of new-mown hay. It is easily extracted from the Tonka-bean by digesting the wdered seeds in alcohol. On evaporating the alcopowdered seeds in anomon. On the problem of holic solution, crystals of commarin are obtained, which may be decolorized by digestion with animal charcoal and subsequent recrystallization. It melts at 122 boils at 518°, at which temperature it may be distilled unaltered. Its vapour has an agreeable aromatic It has a burning taste, and is but slightly soluble in cold water : warm dissolves it readily, de positing it in silky crystals as the solution cools. It forms several substitution compounds with chlorine, iodine, bromine, and nitrous acid. A most irregular and somewhat auomalous compound is formed by its union with teroxide of antimony. On treating it with perchloride of autimony dissolved in hydrochloric acid, a compound is formed having a composition indicating the union of an atom of coumarin with an atom of the union of an atom of coumarin with an atom of teroxide of antimony. Boiled with a solution of potash, coumarin assimilates the elements of water, and becomes transformed into coumario acid, which mitted with the potash. Coumaric acid is obtained in brilliant transparent plates by decomposing a solution of coumarate of potash with hydroculoric acid.

COUNCIL, koun'-sil (Lat. concilium, Fr. concile), in a general sense is a number of persons summoned or convened together for consultation or advice. In modern politics, it is generally used to designate an assembly intended to assist the sovereign, and composed of members whose chief business it is to discuss, advise, legislate, or decide; it being the duty of the ministers to execute. In England, Alfred, to whom we are indebted for so many wise institutions, had three councils, through which all the business of the nation passed. The first was a select council, to which only those high in the king's confidence were admitted, corresponding to the present council. The third was the wittenagement, or general council of the nation, which was inde-

#### Conneil

pendent of the king. In the present day, the queen has a variety of councils to select her in the discharge of her duties, the maintenance of her dignity, and the exercise of her prerogative. The first of these is the high court of parliament (which see): 2. the pears of the realm, who are by their birth hereditary counsellers of the crown, and may be called together by the sovereign to impart their advice in all matters of importance to the realm, either in time of parliament, or, as has been their principal use, when no parliament is in being. A third council belonging to the queen is, according to Sir Edward Coke, her judges of the courts of law for law matters. But the principal council belonging to the queen is the privy council (which see), which is generally, by way of eminence, called the council. The cabinet council (which see) is composed of the more distinguished members of the privy council, to the number usually of about fifteen.

COUNCIL, in Eccl. Hist., is an assembly of prelates and other spiritual persons convened for the purpose of deliberating and making laws for the benefit of the Church. There are several kinds of councils:—1. General or occumenic councils, which are composed of representatives from all parts, summoned for the setting of points of universal interest; 2. national councils, composed of the bishops or clorgy of one kingdom or state, but whose decisions are not regarded as binding over the Church; and 3. provincial councils, convoked by the metropolitans in their respective districts.

The earliest councils were provincial; but sometimes clergy from distant parts attended, in consequence of express invitation. The metropolitan, as president came to acquire great influence in the provincial council, which at length became little more than an organ in his hands. Presbyters as well as bishops were admitted to deliberate and vote, and deacons were also present; but it is matter of doubt whether they were allowed to vote. Some are of opinion that the laity even had seats and votes in the early councils. The number of councils which have been held at various times is very great, amounting, according to some authorities, to 1,500 or 1,600. Of general or com-menical councils, the number is by no means so great; but the different churches are by no means agreed as to what are to be regarded as such. The Greek church only acknowledges seven, and the Roman Catholics reckon eighteen; but even the different sections of the latter church are not agreed as to the individual councils that are to be included in the list. The French reject those of Lyons, Fiorence, and the Fifth Lateran, and receive in their stead those of Pisa, Constance, and Bâle, which the Italians reject. The following is a list of the general councils according to the Roman church : the first eight were called by the emperors. and the rest by the popes. The principal of them will be found more particularly noticed under their own names in other parts of this work. 1. The Council of Nice, which was convened at the city of that name in 325, and which condemned the Arian heresy and drew up the creed known as the Nicene; 2. the first Council of Constantinople, which was convoked by the emperor Theodosius the Great in 381, and which confirmed more definitely certain points of the Nicene creed against the Arisus, and condemned the Macedonian heresy of doming the division of the Nicene creed heresy of denying the divinity of the Holy Ghost; 3, the Council of Ephesus (431), which condemned the Nestorian heresy; 4, the Council of Chalcdon (451), which condemned the errors of Eutyches and Dioscorus, who affirmed that Jesus Christ had but one nature; 5. the Second of Constantinople (553), which condemned the doctrines of the "Three Chapters" (see Chapters, Three) and the heresies of Origen, Arius, Macedonius, and others; 6. the Third of Constantinople (680) confirmed the canons of the five previous councils, and condemned the heresy of the Monothelites, which asserted that there was only one will in Christ; 7. the Second of Nice (787) condemned the Iconoclasts, and sanctioned the worship of images in the churches; 8. the Fourth of Constantinople (869) confirmed the worship of images, deposed Photius from the see of Constanti-

ninges, deposed from the see of consistant nople, and restored Innabus; 9. the first Council of Lateran (1123) decreed that investiture was the soloma right of the Church; 10. the second Council of Lateran (1139) confirmed the election of Pope Innocent II.,

571

and condemned the heresies of Peter de Bruis and Arnold of Breecis; 11. the Third Lateren (1179) condemned the "errors and impisties" of the Waldenses and Ahigenses; 12. the Fourth Lateren (1215) took up many points of mbrality, and condemned various heresies; 13. the first Council of Lyons (1246) ordered a new crusade for the recovery of the Holy Land, and excommunicated Frederick II. of Germany; 14. the Second of Lyons (1274), for reforming discipline and this morals of the clergy, and effecting a union with the Greek church; 15. the Council of Vienne (1311) condemned the order of the Templars, and confiscated demned the order of the Templars, and confiscated their property; 16. the Council of Pias (1409) deposed Gregory XII. and Benedict XIII., and elected Alexander in their stead; 17. the Council of Constance ander in their stead; 17. the Council of Constance (1414) deposed the three contending popes and elected Martin V. in their place, and condemned the doctrines of Huss, Wickliffe, and Jorome of Prague; 18. that of Basie (1431), called to effect a reform in the Church, or Basis (1431), cased to enert a reform in the Church; and to bring about a union with the Eastern church; 19. the Council of Florence (1439) effected a reconciliation between the Eastern and Western churches; but the act was afterwards disavowed by the great body of the Eastern church; 20. the fifth Lateran council (1512), for the suppression of the pragmatic sanction (which see), and the strengthening of the power of the Roman see; 21. the Council of Trent (1545), for the reformation of ecolesiastical abuses and the condemnation of the reformed principles. (See SYNOD.)

COUNCIL OF WAR is an assemblage of the principal officers of a fleet or an army, summoned by the admiral or general, for deliberation or consultation, or to assist him by their advice.

COUNCIL, TOWN. (See TOWN COUNCIL.).
COUNSEL, or COUNSELIOR, koun'-sel, is, a person retained by a client to plead his cause in a court of judicature, or to advise him privately, as it is called, in chambers, although the etiquette is not to receive instruction from reading adjunt account through instructions from or to advise a client, except through the intervention of an attorney, solicitor, or proctor. Among the civilians, counsel are called advocates; but in the courts of common law and equity, there are two species or degrees,—barristers and serjeants. The former we have dealt with under the word BARRISTER, and we shall treat of the latter in the proper place. From both these degrees some are usually selected to be her Mujesty's counsel learned in the law, the two principal of whom are her Majesty's attorney and solicitor-general. Queen's counsel must not be employed in any cause against the crown, without special license. A custom has of late years prevailed of granting letters-patent of precedence to such barristers as the crown thinks proper to honour with that mark of distinction, whereby they are entitled to such rank and pre-audience as are assigned in their respective patents; sometimes after the queen's attorney-general, but usually next after her Majesty's counsel then being. These, as well as the queen-consort's attorney and solicator-general (when the sovereign is a king), rank promiseously with the king's counsel, and, together with them, sit within the bar of the respective courts, but are not sworn, and therefore are at liberty to be retained in causes against the crown. A counsel cannot maintain an action for his fees, which are given not as locatio vel conductio, but as quiddam honorarium; not as a salary or hire, but as a mere gratuity. He is not answerable for any matter spoken relative to the cause in hand, and suggested in his client's instruc-tions, although it should reflect upon the reputation of another, and even prove absolutely groundless; but if he mentions an untruth of his own invention, or even if he mentions an untruth of his own invention, or even upon instructions, if it be impertinent to the cause in hand, he is then liable to an action from the party injured; and counsel guilty of deceit or collusion are panishable with imprisonment for a year and a day, and perpetul silence in the courts. Practising barristers are exempt from serving on juries, as parish constables, and are privileged from arrest in civil cases, whilst entire to staying at any returning from the whilst going to, staying at, and returning from, the apperior courts, quarter sessions, and, if previously retained, petty sessions. (Seg ADVOCATE, BARRISTER, SERTRANT-4T-LAW.)

Count, kount (Fr. conte, Lat. comes), is a title of dignity intermediate between duke and baron, and is, 575

properly, a nobleman who owns a domain spected into a county; but sometimes ambassadors and pienipotentiaries are styled counts without possessing the necessary territory. In England the title has never been used, sithough comes is regarded as the Latin equivalent for earl, and from a very early period the title countess has been given to the wife of an earl. In the times of the Roman republic the inferior officers, engh as the tringer preferts. For were known as the as the tribunes, prefects, &c., were known as the comites of their principal. As a title of dignity it was first used during the reign of Constantine, who, upon the foundation of the new capital, bestowed the dignity of comes upon ten out of thirty-five provincial generals. The Germans, Franks, and other nations vetsined the title, applying it principally to the governors of cities, just as duces, or dukes, designated those noblemen that were in command of provinces. During peace they administered justice, in war they commanded in the army. Under the last of the second race of French monarchs, the dignity became hereditary. In Germany, a count is called graf. (See GRAF.)
COUNT (Fr. compte), in Law, signifies the declaration

of the complainant in a real action. As declaration is applied to personal, so count is applied to real causes; but count and declaration are oftentimes confounded and made to signify the same thing; so the divisions of, or separate statements or allegations in, a declaration, indictment, or criminal information, are called

counts.

COUNTENANCE, kown'-ten-ans (Fr. contenance), the whole form of the human face, or system of the features.

COUNTER-IERITANTS, kown'-ter-ir'-rit-ants (Lat. con-tra, against), in Med., are certain substances applied: ra, against, in Alexi, are contain automated agrants to the skin in order to produce irritation at some distance from a diseased part, with a view to withdraw the inflammation or unnatural action from it. The slightest class of counter-irritants are rubefuncts, or such as merely redden the skin; vertoants, or such as produce vesicles or blisters, are a more powerful. class, and not only cause counter-irritation but prove evacuant; pyogenic counter-irritants, or suppurants, are still more evacuant. Setons, issues, and the actual cautery, also belong to the class of counter-irritants. There is no more valuable remedial agent than counter-irritation, and none more frequently employed with the best results; but it must be rightly timed and placed, not too soon, nor yet too near the seat of the disease. It should not be had recourse to until all acute action has fully subsided, otherwise it may not only fail in affording relief, but may aggravate the local and general disease. It should also be applied at some distance from the site of the original disorder, and yet not too far removed from it.

COUNTERMINE, kown'ter-mine (Lat. contra, Fr. contra, against; mine, mine), in Mil, when an attacking force are engaged in driving the gallery of a mine under any part of the fortifications of the besieged, the latter often drive another gallery towards the enemy's mine to destroy it, and prevent the injury which would be caused to their works if the mine exploded.

Counsel to their works it the mine expoded.

Countiberoint, koun'-ter-point, literally, point against point; so called from the points formerly employed in music instead of notes,—an important branch of musical science, which consists in the art of countries. posing music in several parts either for a variety of voices or instruments; now synonymous with harmony, and nearly so with composition; the only difference being, that composition implies more of invention and being, that composition implies more of invention and of imagination than counterpoint. The invention of the latter is involved in great obscurity; by some it is attributed to Guido (a native of Tuscany, who was born about 900); but, although he was the first to write on this subject, which had made little progress before his time, it is obvious that it was known to several of the earlier musicians. Its real origin appears to have been as follows:—When the organ was accompaniment to the voice, it gave a facility for producing several sounds simultaneously. This soor producing several sounds simultaneously. This soor led to the discovery that there were some sounds agreeable effects: the minor third appears to have been one of the first of these. Other harmonies were also used, which (without mentioning those em-

## Counterscarp

ployed by several authors before Guido) show the origin of the art, and at the same time prove it to have been totally unknown to the ancients. Primitive have been totally unknown to the ancients. Frimitive conticepoint is now called plain for simple counterpoint, to distinguish it from the modern figured or florid counterpoint, in which the melody is beautified and the general effect enriched by the frequent introduction of many successive notes in one part against a single note in another. When the laws of counterpoint began to be understood, you music came to be divided into the part of the laws of which was denominated into four parts, the lowest of which was denominated fewar, the next counter tenor, the third metotus, and the highest desplam and treble. About the middle of the 15th century these parts were increased to six, and were called bass, baritone, tenor, contracto, mezzosoprano, and soprano.

COUNTERSCAIR, koun'-ter-skarp (Fr. contre, against, or opposite; escarpe, scarp), in Mil., that side of the ditch which is opposite the rampart and the scarp below it. To form the outline of the counterscarp of the main ditch of a fortress opposite any of its sides, formed by two semi-bastions and the curtain between them, ares of circles should be described in front of the salient angles of the bastions from the angles themselves as centres, and a tangent drawn to the arc in front of each bastion from the shoulder of the other. These lines meet in a point in front of the curtain, which is called the angle of the counterscarp. ditch is thus contrived that it may be swept by cross-fires from the flanks. The counterscarp of a ditch wound an outwork is parallel to the rampart. Some-times it is revetted with masonry, and very steep; but if it be constructed to admit of a hasty sortic being made on the enemy by the garrison, it should slope in a gentle incline from the bottom of the ditch.
COUNTERSIGN, kown'-ter-sine (Lat. contra, against

signum, sign), the name given to a watchword selected by the officer in command, and privately communicated to the guards and sentries posted about a camp, or at the entrance to a fortress, who have strict orders not to allow any one to pass into the citadel, or within the lines, unless he can give this word, and thereby show that he has the authority of the commanding officer to enter.

COUNTER-TENOR CLEF, kown'-ter-ten'-or klef, in us., the name given to the C clef when placed on the third line, in order to accommodate the countertenor voice.

COUNTER-TENOR VOICE, vois, a term applied to the above G gamut to B or C above the treble clef note.

COUNTING-House, kown'-ting hows (Ang.-Sax.), the house or room specially appropriated by merchants, traders, and manufacturers, to the purpose of keep-ing their books, accounts, letters, and papers.

Country Dance, kun'-tre (Fr. contre danse), a lively pointed air, carculated for dancing. It is of French origin, and was at one time so popular as to be transplanted into almost every country in Europe. There are no established rules for the composition of airs to this dance, neither is it confined to any particular measure, so that any common lively song-tune may be adapted to it.

COURTY, koun'-te, in British Geog., meant at first but at the present time it is a term, so far as England and Scotland are concerned, synonymous with shire, the latter word coming from the Saxon, and the former from the French. In Ireland the term shire is not used as an equivalent of county; neither would it appear to be so used in the English colonies, or in the states of North America. Some of the English counties are almost identical with the old Saxon kingdoms Some of the English coun-As a territorial division, the county is a comparatively late introduction into Scotland; whilst in Ireland its recognition is still more recent. In all the counties of England, with the exception of Durham, Westmoreland, and Cumberland, sheriffs are appointed every Michaelmas term for the execution of the laws. The command of the militia of a county is vested in the lord-lieutenant. Other county officers are: —Justices of the peace, custodes ratulorum, high constable, bailiffs, and coroner. In England there are fifty-two counties, three of which, Lancaster, Chester, and Durham, are called counties palatine (from palatium, 576 •

#### Court

palace), because the chief officer had originally regapowers, or power to administer justice equal with the exercised by the monarch in his palace. Scotlan contains thirty-three counties; Ireland thirty-two.

COUNTY CORPORATE, in England, is a term applied to several cities or boroughs which, in consequence of extraordinary privileges, are enabled to form counties by themselves.

County Cours. (See Cours.)
Coup, koo (Fr., a blow), is a term used in various ways to convey the idea of promptness and force.
Coup d'état is a violent and arbitrary political measure;
coup de thédire, a sudden and striking charge in the action of the scene; coup d'œil, in military affairs, a rapid conception of the weakness and advantages of certain resilience. certain positions or arrangements of troops; coup de main signifies a vigorous, prompt, and decisive military attack.

COUPLET, kup'-let (Fr.), a pair of rhymes, two verses; a division of a hymn or ode, in which an equal number or equal measure of verses is found in each purt, called a strophe.

COUPONS, koo'-pon(g)s (Fr. couper, to cut), in Finance, is a term applied to any cheque, or other piece of paper, cut off from its counterpart. In a special sense, coupous are dividend or interest warrants, which are presented for payment by holders of debentures. All coupons in Great Britain must now bear a stamp,

COURANT, koo-rant' (Fr. courant, running, from Lat, currere, to run).—In Her., when any animal, such as a deer or a dog, is drawn running at full speed, it is described as conrant.

COURTER, koor'e-er (Fr.).—There are two classes of couriers,—public and private. Public couriers are employed by the government to carry dispatches expeditiously and safely to and from the ambassadors at foreign courts. They are accustomed to travel, able to speak several languages, and always ready, at a moment's notice, to set out either on horseback, by hired carriage, or by rail, night or day. They are acquainted with all the regulations of passporis, &c. Private couriers are servants employed by the opulent, when travelling in foreign countries, to facilitate their route, by going before to make preparations, and by looking after their lodgings and general accommodation.

Coursing, koars'-ing (Lat. curro, I run), the sport of hunting hares with greyhounds, which follow the game by sight and not by seent. The breed of greyhounds has greatly improved in this country, and coursing has become very popular. Coursing meetings are held in open parts of the country where here are abundant, and the owners of greyhounds enter their sequential dors for writing talls. A hidden is president. respective dogs for various stakes. A judge is appointed; whose duty it is to decide with respect to the merits of the dogs engaged. The sport then begins by two dogs being selected for a course. They are restrained by the "slipper," a man who holds them by a long strong the "supper," a man who holds them by a long strong cord, with a spring attached to their collars. The field is then beaten for a hare. When it is found, it is allowed 80 to 100 yards start, or "law," as it is called; the judge then gives the word "go," and the slipper frees the dogs by means of the spring. The judge follows the greyhounds through the whole course, and awards the victors to the dog which shows the freest nonway the greynounds through the whole course, and awards the victory to the dog which shows the great qualities of speed, endurance, and sagacity, and not necessarily to the dog which kills the hare. Coursing is of great antiquity, and is treated of by Arrian, who flourished a.D. 150. It was first practised by the Gauls, and was a popular sport with the ancient Greeks.

COURT, koart (Sax. curt, Lat. curia, a senate-house), originally meant the place inclosed by the buildings of a feudal castle; afterwards it came to denote the re-tinue or council of a sovereign. (See ROYAL HOUSE-

-In Law, a court is defined to be a place wherein justice is judicially administered; and as by our excellent constitution the sole executive power of our excellent constitution the sole executive power of the laws is vested in the person of the sovereign, it will follow that all courts of justice (which are the medium by which she administers the laws) are derived from the power of the crown; for, whether created by set of parliament or lotters patent, or subsisting by pre-scription (the only methods by which any court of judicature can exist), the queen's consent in the former

# Court, Admiralty

these couris the sovereign is supposed, an contempla-tion of law, to be always present; but as that is, in fact, impossible, she is there represented by her judges, whose power is only an emunation of the royal pre-rogative. For the more speedy, universal, and impar-tial administration of justice between subject and subject, the law has appointed a prodigious variety of courts,—some with a more limited, others with a more extensive jurisdiction; some constituted to inquire only, others to hear and determine: some to deterextensive jurisdiction; some constituted to inquire only, others to hear and determine; some to deter-mine in the first instance, others upon appeal, and by way of review. All these in their turns will be taken notice of in their respective places; but we may here mention one distinction that runs throughout them all; viz., that some of them are courts of record, others not of record. A court of record is that where the acts and judicial proceedings are enrolled on parchment for a perpetual memorial and testimony, which rolls are called the records of the court, and are of such high and supereminent authority, that their truth is not to be called in question; for it is a settled rule and maxim, that nothing shall be averred against a record, nor shall any ples, or even proof, be admitted to the con-trary. And if the existence of a record be denied, it shall be tried by nothing but itself; that is, upon inspection whether there be any such record or no, otherwise there would be no end of disputes; but if there appear any mistake of the clerk in making up the court will direct him to amend it. All courts of record are the queen's courts, in right of her crown and royal dignity; and therefore every court of record has authority to fine and imprison for contempt of its authority; while, on the other hand, the very erection of a new jurisdiction, with power of fine or imprisonment, makes it instantly a court of record. But the courts not of record, or those of them, at least, in which the common law is administered, are of in ferior dignity; and, in a less proper sense, the queen's courts, and these are not intrusted by the law with any power to fine or imprison the subjects of the realm, unless by the express provision of some act of parlia-ment. In these also the proceedings are not enrolled or recorded; but as well their existence as the truth of the matters therein contained, shall, if disputed, be tried and determined by a jury. In every court there must be, at least, three constituent parts,—the actor, reus, and judgs; the actor, or plaintiff, who complains of an injury done; the reus, or defendant, who is called upon to make satisfaction for it; and the judex, or iguicial power, which is to examine the truth of the lact, to determine the law erising on that fact, and, if any injury appears to have been done, to ascertain, and, by its officers, to apply the remedy. (As to appeals against the decision of different courts, see APPEALS.)

COURT, ADMIRALTY. (See ADMIRALTY.)
COURT, ARCHOPACON'S, is an ecclesiastical court, but the most inferior in the whole ecclesiastical polity. It is held before a judge appointed by himself, and called his official. Its jurisdiction, until the establishment of the Court of Probate, comprised the granting of probates and administrations. It has jurisdiction over sectesiastical causes in general arising within the court of the posts and administration of the posts of the archdeaconry, and in ordinary cases the party may commence his suit either in this court or the bishop's, though in some archdeaconries the suit must be com though in some archdeacouries the suit must be commenced in the former, to the exclusion of the latter. From the archdeacours court an appeal lies, by 24 Hen. VIII. c. 12, to that of the bishop.

COURT OF ARCHEN. (See ARCHEN.)

COURT OF BANKEREN. (See ARCHEN.)

COURT OF BANKERPTCY.—Jurisdiction in cases of bankruptcy is committed to certain commissioners and the the court of the court courts.

to the judges of county courts (except those of the metropolitan county courts), with a final appeal to the lords instices. There is also a subordinate jurisdiction given to the registrars of the several courts. The courts of the commissioners are held in the principal, or London district, in Basinghall Street, and the district courts are held in several previncial towns. The anbordinate powers of the registrars are defined by the Bankruptor Act of 1861, secs. 52 and 58; but they have no power to commit or to hear a disputed adjudication, or any question of the allowance or sus-

# Court of Common Pleas

pension of an order of discharge. The London conf as the power to transfer the proceedings from has the power to transfer the proceedings from one district court to another, or to a county court, and the majority in number and value of the creditors may resolve that the proceedings shall be transferred to the county court of any district other than the metro-politan district; and the court is to order the same accordingly. As we have before to some extent treated of the law of bankruptcy, and incidentally of the powers of the court, the reader is referred to the title Bankruptcy. RUPT.

Court Baron is a court incident to every manor in the kingdom, to be holden by the steward within the manor. This court baron is of two natures: the one a customary court, appertaining entirely to copy bolders, in which their estates are transferred by surrender and admittance, and other matters relative to their tenure only; the other is a court of common law, but not one only; the other is a court of common law, but not one of record, and is before the freeholders who owe suit and service to the manor, the steward being rather the registrar than the judge. It may hold pleas of any personal actions, of debt, trespass, on the case, or the like, where the debt or damages do not amount to forty shillings. But the proceedings may be removed into the superior courts, and, after judgments given a writ of false judgment lies to the courts at Westminster, to rehear and review the cause: which dirrumminster, to rehear and review the cause: which dirrumminster, to rehear and review the cause; which circumstances being productive of great veration and delay, this court has now fallen into disuse. (See COURT OF THE HUNDRED, and the statute there quoted.)
COURT, CENTRAL CRIMINAL. (See CENTRAL CRIMI

NAL COURT.)

COURT OF CHIVALRY is a court military held before COUNT OF CHIVALEY IS A COURT MALLEY HELD CALLEY HELD CALLEY HE CALLEY HELD COURTACE AND OTHER THAN COURT HELD CALLEY HELD CALL chivalry, and afterwards during our connection with the continent by the territories which our princes held in France, but has long since fallen entirely out of use, on account of the feebleness of its jurisdiction and want of power to enforce its judgments, as it can

want of power to enforce its judgments, at coan neither fine nor imprison, not being a court of record.

COURT OF THE CINQUE PORTS.—These have an exclusive jurisdiction (before the mayor and jurats of the ports), in which exclusive jurisdiction the queen's ordinary writ does not run. A writ of error lies from the mayor and jurats of each port to the lord warden of the Cinque Ports in his Court of Shepway, and from that to the Queen's Bench. (See CINQUE PORTS, and

Courts, Shepway.) COURT OF THE CLERK OF THE MARKET .- This court is the most inferior court of criminal jurisprudence in the kingdom; but is incident to every fair and market therein, to punish misdemeanours committed in such fair or market, as a court of pied poudre (which see) is to determine all disputes relating to private or civil property. The object of the jurisdiction is principally he cognizance of weights and measures, to try whether they be of the true standard thereof or not, which standard was anciently committed to the custody of the bishop, who appointed some clerk under him to inspect the abuse of them more narrowly; and hence,

this officer, though in most cases a layman, is called the clerk of the market.

COURT OF COMMON PLEAS, or, as it is sometimes technically called, the Court of Common Beach, is one of the three superior courts of common law, and is a court of record, and in that capacity takes cognizance of all actions between subject and subject, without exception, including formerly the extensive class of real ception, including formerly the extensive class of real actions, of which it still retains the few surviving species. (See ACTION.) And over remedies of this kind (which formerly excelled all others in importance) it has always exercised an exclusive jurisdiction, as it did also over fines and recoveries, while those modes of assurance existed, and still does over the forms of conveyance now substituted for them. For these reasons, and also because its authority in these matters, we would be a second of the case of the was original, and not usurped (as in the case of the Exchequer and Queen's Bench), it has always been considered as the principal seat of the learning relative to ordinary actions between man and man, and is styled by Lord Coke the lock and key of the common

577

## Court, Consistory

isw. It has the excitaive jurisdiction of deciding questions of law relating to the rights of voters for members of parliament, in cases stated by revising barristers. It has no authority, however, like the Exchequer, in matters relating to the revenue. The judges are at present five in number, one chief and four pulsue justices, and from their decision proceedings in error may be taken into the Exchequer chamber. It is one of the three courts called the misperior courts, or the courts at Westminster, the other two being the courts of Queen's Bench and Exchequer.

COURT, CONSISTORY.—Every diocesan bishop has a court held in his cathedral for the trial of all ecclesiastical causes arising within his diocese, and in which probates and administrations were granted previous to the establishment of the Court of Probate. The bishop's chancellor, or his commissary, is the judge, and from his sentence an appeal lies to the archbishop of the province.

COURT, CONTENT OF.—Contempts of court are either direct, which openly insult or resist the powers of the courts or the persons of the judges who preside there, or else are consequential, which (without such gross insolence or direct opposition) plainly tend to create a universal disregard of their authority. All courts of record are the queen's courts, in right of her crown and royal dignity; and, therefore, every court of record has authority to fine and imprison for conor record has authority to me and imprison for con-tempt of its authority. The principal instances of either sort are the following kinds:—1. Those com-mitted by inferior judges and magistrates, by acting anjustly, oppressively, or irregularly, in administering those portions of justice which are intrusted to their distribution on he discharing the madistribution on he discharing the madistribution. distribution, or by disobeying the royal writs issued out of the superior courts; by proceeding in a cause after it is put a stop to, or removed by writ of pro-hibition, certiorari, error, supersedeas, or the like. 2. Those committed by sheriffs, bailiffs, gaolers, or other officers of the court, by abusing the process of the law, or deceiving the parties by any act of oppres-sion, extortion, collusive behaviour, or culpable neg-lect of duty. 3. Those committed by attorneys and lect of duty. 3. Those committed by attorneys and solioitors. (See ATTORNEY.) 4. Those committed by jurymen in collateral matters relating to the discharge of their office, such as making defaults when aummoned, refusing to be sworn or to give any verdict, eating or drinking without leave of the court, and especially at the cost of either purty, and other misbehaviour and irregularities of a similar kind; but not behaviour and irregularities of a similar kind; but not in the mere exercise of their judicial capacities, as by giving a false or erroneous verdiet. 5. Those committed by witnesses, by making default when summoned, refusing to be sworn or examined, or prevariesting in their evidence when sworn. 6. Those committed by parties to any suit or proceeding before the court by disobedience to any rule or order made in the progress of a cause, or other proceeding; as by non-payment of costs awarded by the court upon a section or by non-payment of costs awarded by the court upon a section or by non-payment of costs awarded by the court upon a section. motion, or by non-observance of awards duly made by arbitrators or umpires after having entered into a rule for submitting to such determination. However, the contempt in such cases as last mentioned is, in general consequential or constructive only; as it implies no setual disregard of authority, but may proceed from the poverty of the party. 7. Those committed by any the poverty of the party. 7. Those committed by any persons in the way of disobedience to the queen's write, or other disrespect to the court's authority, or writing to a judge privately on a matter before the court. Some of these contempts may arise in the face of the court; as by rude and contumelious behaviour by obstinacy, perverseness, or prevarication; by breach of the peace, or any wilful disturbance whatever: others in the absence of the party, as by disobeying or treating with disrespect the sovereign's writ, or the rules or process of the court, by perverting such writ or process to the purpose of private malice, extertion, or injustice; to the purpose of private malice, extortion, or injustice; by speaking or writing contemptuously of the court or indges acting in their judicial capacity; by printing false accounts (or even true ones against the prohibition of the court) of causes then depending in judicial or the court of causes then depending in judicial to the court in the performance of his duty, or treating the process of the court with actual disrespect or contempt; and by anything, in short, that demonstrates a gross want of that regard and respect which, when

# Court of Mischequer Chamber

once courts of justice are deprived of their authority (so necessary for the good of the kingdom) is entirely lost among the people. (See ATLORERET, COMMET. MENT.

COURT OF THE CORONER is a court of record, inquire into the matters referred to under the article COROWER, in loco. As there stated, his principal dut-CORONER, in loco. As there stated, his principal duty is to inquire into the deaths of parties, and in general be ought to hold his court super visum corporis, upon view of the body.

COURT, COUNTY .- The County Court; as it exists at common law, and independently of the branch new added to it by etatute, is a court incident to the jurisdiction of the sheriff. It is not a court of record, but might entertain all personal actions to any amount by wirthe of a special writ, called a justiceies, issued out of the common-law side of the court of Chancery. This power was taken away on the establishment of the new county courts. The freeholders of the county are the real judges in this court, and the shoriff is the minis-terial officer. terial officer. All outlawries of absoonding offenders are there proclaimed, and all popular elections, as of coroners, verderers, and knights of the shire, must be made in plene comitate, or in full county court. Proceedings are removable from hence into the superior courts by writ of pone or recordari, in the same manner as from hundred courts and courts baron; and the

ner as from indired courts and courts and the same writ of false judgment may be had in the nature of a writ of error. (See reference in Courts, Bonoven.) Court, Customart, is distinct from the Court Baron (although usually held at the same time). The Court Baron is that of the freeholders of a manor, whilst the Customary Court is that of the copyholders or customary tenants. It is held before the lord or lady of the manor, the steward, and a jury, culled the homage, or homage jury, who are tenants of the manor. The chief business at these courts is to admit tenants to their property on the death or alienation of the preceding tenant. The jury make presentments of de-faults and deaths of tenants, and assess fines for admittance of the tenants.

COURT OF DELEGATES was formerly the great court of appeal in all ecclesiastical courts, but its functions have been superseded by the Judicial Committee of have the Privy Council.

COURT OF EXCURQUER was at first intended principally to order the revenues of the crown, and to recover the king's debts and duties, though it has since acquired, and originally by usurpation, the additional character of an ordinary court of justice between subject and subject. It is called the Exchequer (seacourium) from the chequered cloth, resembling a chessboard, which covered the table there, and on which, when which covered the tang's accounts were made up, the mans were marked and scored with counters. It consists of two divisions,—the receipt of the Exchequer, and the court or judicial part of it. It formerly had jurisdiction as a court of equity; but this was transferred to the court of Chancery, except in matters of revenue. It is therefore now a court of revenue and a court of common law. In the former capacity it ascertains and enforces, by proceedings appropriate to the case, the proprietary rights of the crown against the subjects of the realm; in the latter it administers redress between subject and subject in all actions whatsoever, except in the few species of real actions which still survive the general demolition of that class. These are exclusively under the jurisdiction of the court of Common Pleas. the court of record, and its judges are five in number, consisting of one chief barons and four pushes barons, as in this court the judges are termed. It is one of the three courts called the superior courts, or the courts at Westminster, the other two being the court of Common Pleas and the court of Queen's Bench.

COURT OF EXCHEQUEE CHAMBER.—This is a court of appeal to correct the errors of other jurisdictions. of appeal to correct the errors of other jurisdictions. It exists—I, as a court of mere debate, such coases from the other courts being sometimes adjourned into it as the judges, upon argument, find to be of great weight and difficulty, before any judgment is given by them in the court below. It then consists of all the judges of the three superior courts of common law, and now and then the lord chancelor size. As a court of error. It they consists of the indees of the court of error. It then consists of the judges of the two superior courts other than that whose judgment

## Court Fool

is appealed against, sitting collectively as a court of error in the Exchequer chamber to revise such judg-ment. A writ of error lies from this court to the House of Peers.

Court Foot, a jester much employed in ancient times by nobles and wealthy persons, to enliven the time by jests and witty remarks. During the Middle Ages, the court fool became an indispensable officer. Ages, the court fool became an indispensable officer. He assally had his head shaved, and wore a fool's cap of gay colours, with ass's ears and a cock's comb. He often had bells attached to his cap, and earried a scentre variously formed. The dress, however, generally depended on the caprice of his master. Triboulet, the court fool to Francis I., king of France, obtained an historical reputation, as did also his successor Brusquet. English court jesters disappeared with the Stuart dynasty; one of the last examples being Armstrong, who died in 1646. Afterwards half-witted persons were employed as court fools by noblemen; but towards the end of the 17th and the beginning of the 18th century the custom was entirely abolished.

18th century the custom was entirely abolished.

COURT OF HIGH COMMISSION.—This was a court in causes ecclesiastical. It was erected and united to the legal power by virtue of the statute 1 Eliz. c. 1, and was intended to vindicate the dignity of the Church by reforming, ordering, and correcting the ecclesiastical

retorning, ordering, and correcting the eccessasticas state and persons, and all manner of errors, heresies, schisms, abuses, offences, contempts, and enormities. It was abolished by statute 16 Chas. I. c. 11.

Court of the Hundred is only a larger court baron, being held for all the inhabitants of a particular hundred, instead of a manor. The free suitors are liere also the judges, and the steward the registrar, as in the case of a court baron. Causes are equally liable to removal hence, and may be reviewed, as in the court baron, and in practice no resort to this court is ever made. By the 9 & 10 Vict. c. 95, s. 14, provision is made enabling the lord of any hundred, or of any hundred, are necessarily approached to the proper or liberty having any court in right honor, manor, or liberty, having any court in right thereof in which debts or demands may be recovered,

to current ment upits or temands may be recovered, to current to her Majesty the right of holding such court, after which it shall be discontinued.

COURT OF HUSTINGS. (See COURTS OF LONDON.)

COURT OF HRQUINY.—On some occasions, the crown directs a court of inquiry to be held in cases of breach of the Articles of War, the object of which is to ascertain the propriety of resorting to ulterior proceedings against the party charged.

COURT-LEET, OF VIEW OF FRANKPLEDGE, is a court of record, and held once in the year, but not oftener, within a particular hundred, lordship, or manor, before the steward of the leet. Its original intent was to view the frankpledges, that is, the freemen within the liberty. Besides this, the preservation of the peace and the chastisement of divers minute offences are its objects. The jurisdiction of the court is the same as that of the Sheriff's Tourn, or ancient County Court, and extends from common nuisances, and other material offences against the peace and public trade, down to eaves dropping, waifs, and irregularities in public commons. The court has grown into a state of desuctude, by reason of its holding its session so seldom, and of the business, for the most part, having devolved upon the quarter sessions.

COURT, LORDS JUSTICES' .- This is a court of appeal in Chancery, and consists of the lord chancellor and two judges, called the Lords Justices, and possesses all the jurisdiction exercised by the lord chancellor himself, so far as his judicial business in Chancery is conself, so far as his judicial business in Chancery is conserned, without prejudice, however, to his right to sit, as formerly, alone. To this court (the powers of which may be exercised not only by its full body but by either of its judges), together with the lord chancellor, or by both the judges apart from the lord chancellor, an appeal from the master of the rolls and each of the rice-chancellors may be referred, or may be entertained by the lord chancellor alone, sitting in his proses intradiction; and from these annellate invisions. per jurisdiction; and from these appellate jurisdic-tions an appeal in turn lies to the House of Lords. This is also the court of appeal in matters in bankruptcy

COURT OF OYME AND TREMINER, and General Gaol Delivery. The jurisdiction of this court will be found under ASSIZES.

COURT OF PARLIAMENT .- The high court of parliaent is the supreme court of the kingdom, not only for 579

# Court of Quarter Session

the making, but also for the execution of the laws, the trial of great and enormous offenders, wheth lerds or commencers, in the method of parliamenta impeachment. (See laws account of ledy the Queen in Parliament is held during the seek of parliament for the trial of an indicted poer, (See

LORDS, HOUSE OF.)
COURT OF PROVILLES is a branch amered to the COURT OF PECULIARS 18 a branch america to the Court of Arches. It has a jurisdiction over all those parishes dispersed through the province of Canterbury, in the midst of other dioceses, which are exempt from the ordinary's jurisdiction, and subject to the metropolitan only. All ecclesiastical causes arising within these peculiar or exempt jurisdictions are originally cognizable by this court, from which an appeal lies to

COURT OF Arches.
COURT OF PIED POUDER, OF FIE POWDER (curia pedia pulverizati), so called from the dusty feet of the suitors; or, according to Lord Coke, because justice is there done as speedily as dust can fall from the foot. But the etymology given us by a learned modern writer (Barrington's Observations on the Stat. 337) is much more ingenious and satisfactory; it being derived, according to him, from pied puldreaux (a pediar, in Old French), and therefore signifying the court of such petty chapmen as resort to fairs or markets. It is a court of record incident to every fair and market, though fallen into disuse, and now in a manner for gotten, of which the steward of him who owns or has the toll of the fair or market is the judge; and iss jurisdiction extends to administer justice for all com-mercial injuries done in that very fair or market, and not in any preceding one; so that the injury must be done, complained of, heard, and determined within the time during which the fair or market is held. court has cognizance of all matters of contract that can possibly arise within the precinct of that fair or market; and the plaintiff must make oath that the cause of action arose there. From this court a writ-of error lies in the nature of appeal to the courts at Westminster. The reason of its original institution seems to have been to do justice expeditiously among the variety of persons that resort from distant places to a fair or market, since it is probable that no inferior court might be able to serve its process, or execute its judgments, on both, or perhaps either of the parties; and therefore, unless this court had been exected, the complainant must necessarily have resorted, even in the first instance, to some superior judicature. Courts similar to the pie-powder courts were usual both with Greeks and Romans, who introduced fairs into Ger-many and the North.—Ref. Fosbroke's Dictionary of Antiquities

COURT, PRESENTATION AT. (See PRESENTATION AT COURT.)

COUPT OF THE PRIVY COUNCIL is the great court of appeal in all ecclesiastical causes, and those from the colonies, and was substituted for the former appeal colonies, and was substituted for the former appear court, viz. the Court of Delegates, which was composed of commissioners appointed under the great seal: Practically, all the judicial authority of the privy council is now exercised by a committee of privy councillors, called the Judicial Committee of the Privy Council, who hear the allegations and proofs and make their report to her Majesty in council, by whom the judgment is finally circumstants. given.

COURT OF QUARTER SESSION, or General Quarter Sessions of the peace, is a court that must be held in every county once in every quarter of a year, in the first week after each of the following days,—the 11th October, the 28th December, the 31st March, and the 24th June, before two or more justices of the peace, one of whom must be of the quorum. The jurisdiction of the court extends to the trying and determining of all felonics, misdemeanours, and trespasses, except all felonies, misdemeanours, and trespasses, except treason, nurder, or capital felony, which, when com-mitted by a person not previously convicted of felony, is punishable with transportation for life, and except certain other offences enumerated in the acts of 4 & 5 Vict. c. 88, of 5 & 6 Vict. c. 38, and 9 & 10 Vict. c. 25. Lts jurisdiction comprises offences relating to the game. laws, highways, alchouses, bastard children, the settle-ment and provision for the poor, servants' wages, and apprentices. Some of these are proceeded upon by indictment, and others in a summary way, by motion, and

# Court of Queen's Bench

order thereupon, which proceedings may for the mest part (unless guarded against by particular statutes) be removed into the court of Queen's Hench by writ of removed into one course to the court also manages the quashed or confirmed. The court also manages the mancial affairs of the county, and makes county-rates, and makes county and superintends the prisons and paper luntile as-lums in the county. As regards the county of Middle-set, two accisions, or adjourned assessons of the peace, are, by 7 & 8 Vict. c. 71, to be held in every calendar month, and the first sessions in January, April, July, and October respectively, are to be the general quarter assions of the county; and the second sessions in those months are adjournments of the general quarter ions; and a serjeant or barrister-at-law, of not less than ten years' standing, and in the commission of the man ten years standing, and in the commission of the peace for the county, and qualified by law to act as such justice of the peace, is appointed by her Majesty to be the assistant-judge of the court. In many municipal corporations or boroughs, there is also a court of quarter sessions of the peace, having, in general, the same authority in cases arising within the limits of the borough as the county quarter sessions within the county. But of such court the recorder of the borough is the sole judge, and he is to hold the court once in every quarter of a year, or at such other and more frequent times as, in his discretion, he may think fit, or her Majesty may direct. (See Custos Rotu-LORUM.

COURT OF QUEEN'S (or KING'S) BENCH, so called because the sovereign used formerly to sit there in person, the style of this court being coram ipso rege or regind. In the reign of a king it is called the King's Renck, and during the protectorate of Cromwell was styled the Upper Bench. It is a court of record and the supreme court of common law in the kingdom, consisting of a chief justice and four puisne justices, who are, by their office, the sovereign conservators of the peace and supreme coroners of the land. Yet though the sovereign himself used to sit in this court, and still is supposed so to do, he did not, neither by law is he empowered to, determine any cause or motion but by the mouth of his judges, to whom he hath com-mitted his whole judicial authority. The jurisdiction of this court is very high and transcendant. It keeps all inferior jurisdictions within the bounds of their authority, and may either remove their proceedings, to be determined here, or prohibit their progress below. It superintends all civil corporations in the It commands magistrates and others to do kingdom. what their duty requires in every case where there is no other specific remedy. It protects the liberty of the subject by speedy and summary interposition. It takes orgainance both of criminal and civil causes, the former on what is called the crown side, or in the crown office, the latter on the plea side of the court. On the crown side, or in the crown office, it takes cognizance of all criminal cases, from treason down to the most trivial misdemeanour or breach of the peace. Into this court indictments from all inferior courts may be removed by writ of certiorari, and the manner of trial in this court is either at bar (which rarely happens) or at misi prius. On the plea side, or civil branch, it enjoys a general jurisdiction and cognizance over all actions between subject and subject, chose of the real class only excepted, which are entertained by the court of Common Pleas. It does not meddle, however, with matters of revenue, which belong to the court of Exchequer. It is one of the three courts called the superior courts, or courts at Westminster, the other two being the courts of Common Pleas and Exchequer. A writ of error lies from this court to the Exchequer Chamber. (See CERTIORARI.)

Cours. Rolls, is one of the branches of the court of Chargery, presided over by a judge who is called the Marter of the Rolls, and who was originally appointed only, for the superintedence of the writs and records appetraining to its common-law department, tread also the with a positive of the write and records appetraining to its common-law department, records apperranting to its common-isw department, but accustomed also to sit on the equity side as a separate though subordinate judge. He has jurisdiction in all proceedings in equity, except such as, by the course of the sourt, are appropriated to the great seal slone. The set of 1 & 2 Vict. o. 04, vested in him the custody of the public records.

Court of Session. (See Session, Court or.)

# Courts, County

Court of Sawars is a temporary tribunal erected by virtue of a commission under the great real, which formerly used to be granted pro remain at the pleasure of the crown, but now at the discretion and nomination of the lord chancellor, lord treasurer, and chief justices, pursuant to the Statute of Sewers, 28 Hen. 2117.0.6. Their jurisdiction is to overlook the repairs of the hanks and walls of the sea-coast and navigable rivers, or, with the consent of a certain proportion of the owners and occupiers, to make new ones, and to cleanes such rivers and the streams connected therewith, and is confined to such county or particular district as the commission shall expressly name. The commissioners are a court of record, and may fine and imprison for contempt, and, in the execution of their duty, may proceed by jury, or upon their own view, and may take order for the removal of any annoyance, or the safeguard and conservation of the sewers within their commission, either according to the laws and customs of Romsey Marsh, or otherwise, at their own discretion. They may also assess such rates or scots upon the owners of lands within their district as they shall judge necessary; and if any person refuses to pay them, the commissioners may levy the same by sale of his goods and chattels, or sell his freehold or copyhold lands, in order to pay such scots or assessments. By 4 & 5 Vict. c. 45, they are also empowered, for the purpose of defraying such expenses incident to the commission as in the act particularized, to tax in the gross in each parish such lands as are within the jurisdiction, but so that such lands shall contribute thereto in proportion to the benefit received as compared with the lands of the other parishes, which tax shall be denominated the general sewers tax, and be recoverable by distress and sale. Their conduct is under the control of the court of Queen's Bench, which will prevent or punish any illegal or tyrannical proceedings. Before dismissing the subject, it may be noted that Romsey Marsh, above mentioned, is in the county of Kent, forming a tract containing 24,000 acres, and is governed by certain ancient and equitable laws of sewers composed by Henry de Bathe, a venerable judge in the reign of King Henry III., from which laws all commissioners of sewers in England may receive light and direction.

COURT OF SHEPWAY is a court held before the lordwarden of the Cinque Ports. A writ of error lies from the mayor and jursts of each port to the lord-warden in his court of Shepway, and from thence to the Queen's Bench.

COURT, SHERIFFS', or SHERIFFS' TOURN, or rotation, is a court of record held twice in every year, within a month after Easter or Michaelmas, before the sheriff, in different parts of the county; being, indeed, only the turn of the sheriff to keep a court leet in each omy the turn of the sherin to keep a court leet in each respective hundred; this, therefore, is the great court leet of the county, as the County Court is the court baron; for out of this, for the case of the sheriff, was taken the court leet, or view of frumkplede, which see.

COURTS, BOROUGH, were originally founded from the

favour of the crown to particular districts, for the convenience of the inhabitants, that they might prosecute their suits, and receive justice at home. The courts at Westminster have, for the most part, a concurrent jurisdiction with them, or else a superintendency over them. Their proceedings ought to be according to the course of the common law, unless otherwise ordered by parliament. By the Municipal Act, 5 & 6 Will. IV. c. 76, the recorder is to be the judge in any court of record for civil actions in the boroughs to which the act extends, if such court be not regulated by the provisions of any local act; but he may appoint a deputy. visions of any local act; but he may appoint a deputy. From these courts, where they are courts of record, a writ of error lies in general to the court of Queen's Bench. A detailed statement as to all the borough courts, county courts, courts of requests, and other local courts throughout the kingdom (se they existed previously to the 9 & 10 Vict. a. 98), showing the extent of their jurisdiction, the authority under which hav were hald and their form of processes. they were held, and their form of process, &c., will be found in the fourth Report of the Common Law Com-missioners, Appendix, Part II. No. 5. COUNTS OF CHANCELLORS OF THE UNIVERSITIES.

(See Universities.)
Courts, County.—The necessity being felt of establishing throughout the whole kingdom some satisfactory

and uniform plan of proceeding for recovery of all debts and demands below a certain amount, it was conceived that new inferior courts, with improved machinery and that new inferior courts, with improved machinery and an ample jurisdiction, might advantageously be created under the name of County Courts, which should form, as it were, a branch of that ancient and well-known institution. This design was carried out by the statute 9 & 10. Vict. c. 95. By the effect of this act, and of orders of council subsequently made thereon, pursuant to its provisions, the courts of request, which this court was intended to supersede, have in general been abolished. The act provides, that for all purposes, except those within the jurisdiction of the new courts to be holden thereunder, the county courts shall be holden holden thereunder, the county courts shall be holden as before. By the act referred to and subsequent etatutes, the jurisdiction of the county courts extends over England, except the city of London, and has been from time to time materially enlarged. It includes all pless of personal actions where the debt or damage claimed is not more than £50, whether on balance of account or otherwise, or when reduced by set-off under that sum, with the exception, however, of actions of ejectment, or in which the title to any incorporeal bereditament, or to any toll, fair, market, or franchise shall be in question, or in which the validity of any devise, bequest, or limitation under will or settlement may be disputed, except as hereinafter mentioned; or for any malicious prosecution, libel, slander, seduction, or breach of promise of marriage. It also extends to the recovery of any demand not exceeding £50, which is the whole or part of the unliquidated balance of a partnership account, or claimed by way of distributive share under an intestacy, or as legacy under a will. It has concurrent power with the superior courts to give summary judgment in actions upon bills of exchange where the claim does not exceed £50. It has power to proceed in cases of replevin; and the proviso which deprived it of entertaining cases of ejectment was modified in certain cases; but now by 19 & 20 Vict. c. 108, sec. 50, lundlords are enabled, after the expiration of the tenancy, to recover posses-sion of houses, lands, or other corporeal hereditaments, where neither the rent nor the value of the premises shall have exceeded £50 a year, and no fine or pre-mium shall have been paid; and by sec. 51 a claim for rent or mesne profits, or both, may be added; and by sec. 52 a similar jurisdiction is given in cases where half a year's rent is in arrear, and no sufficient distress can be had. The crown may sue in the court for custons duties or penalties not exceeding £100; and an action may be brought therein against custom-house officers for illegal seizure, where the damages claimed do not exceed £50. Parties may, by consent, confer a jurisdiction on the court in any action and for any amount, except in cases of criminal conversation; the right of action for which has, however, in all cases been abolished. It may in certain cases detain foreign ships for damage done in any part of the world to any pro-perty of her Majesty or any of her subjects, until satisfaction is made, or security is given to abide the event of a legal proceeding in respect of it. In the sourt may be recovered the costs of proceeding under the Nuisances' Removal Act, 1855. It has an appellate jurisdiction in cases of awards of surveyors in the ignification in cases or awards or surveyors in the metropolitan district, under the Metropolitan Building Act, 1855, where the matter does not involve the payment of more than £30. It may give relief and make orders in relation to charitable trusts, where the income of a charity does not exceed £30; and entertain (under certain conditions) an appeal against the commissioners in assessing the succession duties, if the sum in dispute does not exceed £50, or the appellant contends that it should be reduced by a sum not exceeding tends that it should be reduced by a sum act exceeding £30. The judges sitting at places more than twenty miles from the General Post-office are appointed commissioners to act under the powers of the Joint-Stock Companies Winding-up Amendment Act, 1849, which is, however, except as to cases of banking and insurance companies, repealed; and to take evidence in winding-up cases, under the Joint-Stock Companies Act, 1856. The court has a jurisdiction in certain cases in hardranter (see BANKBURT); and the content. case in bankruptcy (see Bankrupt); and the conten-tious jurisdiction of the Court of Probate (subject to certain conditions) is extended to it, with power to terrolks a probate or grant of administration in cases

where the personal estate is under the value of £200, and the real estate is under the value of £300. Under and the real estate is under the value of ENO. Under the Copyright of Designs Act, 1852, the proprietes may take proceedings in the court of the district within which any piracy has been committed, for the recovery of damages sustained by reason of the piracy. The judge of a county court may issue his warrant for the supprehension of absconding debtors, sworn to be the debted £20 or upwards (see Anner); and may perform all such duties relating to causes or matters demending in channer, or any indee thereof, or before of m all such under relating to causes or matters depending in chancery, or any judge thereof, or before the chuncellor in the exercise of any authority belonging to him necessary or proper to be done in his district, as the chancellor from time to time by a general order may direct. It will be thus seen that the constitution of these courts has been a great boon to the country, by enabling suitors at a comparatively small expense to by enabling suitors at a comparatively small expense to obtain justice, in a great number of instances, without running the risk of incurring the loss, delay, and yexation of having to resort to the superior courts, which frequently operated as a denial of justice altograther; and there is little doubt but that in process of time, by the gradual enlargement of their jurisdiction, these tribunals will become local justice-seats for the trans-action of all legal business, except that of the superior class, for the determination of which the highest legal acumen may be required.

COURTS OF THE DUCKY OF LANCASTER. (See PALA-

TINE COURTS.)

COURTS OF DURHAM. (See PALATINE COURTS.) COURTS, FOREST .- These have fallen into abs desuctude, although certain branches are courts of record. They consist of the courts of attachment, of regard, of sweinmote, and of justice-seat. As the constitution of these courts is a subject more for the antiquary than the general reader, we consider it unnecessary here to enter upon it.

Course or Lorson.—There are several courts having jurisdiction within the city; but most of them entersian matters peculiar to the government and constitution of the city, as regulated by custom. The principal are the Hustings, which is the ancient county court of London, and held before the lord-mayor, recorder, and sheriffs, and is the principal court of the city. but no actions can be brought in it they are city; but no actions can be brought in it that are merely personal. To this court a writ of error lies from the sheriff's court, and from thence to justices appointed by a commission from the crown (who used to sit in the church of St. Martin's-le-Grand), and from them to the House of Lords .- Lord Mayor's is a court of record held before the mayor and alderman for all actions arising within the liberties of London, in which the recorder is judge, but the mayor and aldermen may join with him when they please. So in this court, all matters of equity within London may be determined upon till and answer, upon which the recorder is also judge. It takes cognizance of appeals from the inferior courts of the city and foreign attachments; as to which, see ATTACHMENT. Since writing that article, the court of Queen's Bench has decided that the court has no jurisdiction unless the garnishes has a residence or carries on business in the city.—Orphans. The mayor and aldermen, in their Court of Orphans, are entitled, according to the custom of London, to the custody of the person, lands, and chattels of every infant wh parent is free of and dies within the city, which custom asts, in the case of males, till twenty-one; of females, till eighteen or marriage. It is said, however, to be fallen into disuse.—Sheriffs'. This is held before their steward or judge, and has cognizance of all pleas of personal actions to any amount, and in which, where the debt or damages claimed shall not exceed £50, a summary mode of proceeding has been recently estab-lished, similar in general to that provided for the new county courts.—See The London (City) Small Debt Extension Act, 1852. COURTS OF LORD HIGH STEWARD. (See STEWARD.)

COURTS OF LORD HIGH STEWARD. (See STEWARD.)
COURTS MARTIAL.—These courts are established by
virtue of an annual act of parliament called the Mutiny
Act. (See ARTICLES OF VAR; INQUIEX, COURT OR.)
COURTS, NISI PRIVE.—These are composed of two,or
more commissioners, called judges of assire and sist
priss, empowered to try all questions of fact issuing
out of the courts at Westminster that are then ripe for
trial by jury; the original of which name is this; all

causes commenced in the courts of Westminster Hall are, by the course of the courts, appointed to be tried on a day fixed in some Easter or Michaelmas term, by a justy returned from the county wherein the cause of action arises, or in which the verue is laid; but with this provise, "nisi prina" justiciaris ad assias capisades venerint; that is, unless, before the day prefixed, the judges of assize come into the county in question (which they always do in the vacation preceding each Michaelmas term) and there try the cause Manior they aways do in the receipt processing of the Master and Michaelmat term), and there try the cause; and then, upon return of the verdict given by the jury to the court above, the judges there give judgment for the pairty for whom the verdict is found; there being, however, as to London and Middlesex, this exception,—

\*\*The Tankad of their being comprised within any circulation. that instead of their being comprised within any circuit, courts of Nies Prine are held there for the same purpose in and after every term before the chief or other judge of the superior courts at what are called the London and Westminster sittings.

COURTS, PALATINE.—These are of a limited local jurisdiction, and have at the same time an exclusive segnisance of pleas in matters both of law and equity, and appertain to the counties palatine of Lancaster and Durham, and are the palatine courts of Common Pleas and of Chancery, and they are courts of record.

Course or Request on Conscience were established in various parts of the kingdom for the recovery of small debts and demands; but they were superseded by the establishment of the new county

COURTS, STANKARY, in Devoushire and Cornwall, are They are courts of record, and held before the lordwarden and his substitutes. All tinners and labourers in and about the stannaries, during the time of their ma and about the stannaries, during the time of their working therein bond fide, are privileged from suits of other courts, and to be only impleaded in the Stannary courts in all matters arising within the stannaries, excepting pleas of land, life, and member. But if a cause of action between tinner and tinner arise out of the stannaries. the stannaries, it may be brought elsewhere, if the plaintiff will (2 Inst. 231, Com. Dig. Courts, 1.1); and panners win (2 Inst. 231, Com. Dig. Courts, I.1); and even if it arise within the stannaries, the plaintiff has the option of bringing it either in the Stannary Court or in the County Court.—(See Newton v. Nancarrow, 15 Q.B. 144.) No writ of error lies from hence to any court in Westminster Hall, but an appeal lies from the plantagement of the load readen, and the contract the vice-warden to the lord-warden, and thence to the privy council of the prince of Wales as duke of Corn-wall, when he has had livery of investiture of the same: and from thence the appeal lies to the king or queen in the last resort. — (See 6 & 7 Will. IV. c. 106, as to workers in lead, copper, &c.)
COURTS, UNIVERSITY (the Chancellor's Courts).-

two universities of England (Oxford and Cambridge) enjoy the sole jurisdiction, in exclusion of the queen's courts, over all civil actions and suits whatsoever, when a acholar or privileged person is one of the par-ties, except in such cases where the right of freehold ties, except in such cases where the right of rection is concerned, provided the defendant is resident there, and provided, in the case of Cambridge, the cause of cambridge or its adults. And these, by the university charter, they are at liberty to try and determine either according to local customs, at their discretion; which has generally local outloms, at their discretion; which has generally led them to carry on their process in a course much conformed to the civil law. This privilege, so far as a relates to civil causes, is exercised in the Chancellor's Court, the judge of which is the vice-chancellor, his disputy or assessor. From his sentence an appeal lies to delegates appointed by the congregation; from the other delegates of the House of Convocation; and if they all three concur in the same sentence, it is similarly at least by the statutes of the university, according inal, at least by the statutes of the university, according to the rule of the civil law. But if there be any discordsince or variation in any of the three sentenges, an appeal lies in the last resort to judges' delegates, appapea lies in the last resort to judges' delegates, appointed by the crown under the great seal in chancery. In original offences, the lord high steward has cognismos of all indictments of treasons, insurrections, stance, and may hear, which shall be found against elemies, and may hear, which shall be found against establish the most blesged word of God and his consciously for the time being; but, when his office is called forth into action, he must be themselves atill more distinctly to mutually support

approved by the lord high chancellor of Bagland, and a special commission is given to him and others to try the indictment then depending, according to the isaw of the land and the privileges of the university. The party charged has no right to have the indictment removed, and the vice-chancellor only can claim cognizance of it, and, when allowed by the judges of assize, it comes to be tried in the High Stewards court. The indictment must first be found by a grand jury, and then the cognizance claimed. When the cognizance is accultoned in the light of the commission of the commission of the commission of the commission is accultant.

court. The indictment must first be found by a grand jury, and then the cognizance claimed. When the cognizance is so allowed, if the offence be a misdemeanour only, it is tried in the Chancellor's Court by the ordinary judge.

COURTS, VICE-CHANCELLORS'.—These are branches of the court of Chancery, and the judges sit (like the master of the rolls) separately from the lord chancellor, and are virtually his assistants. Except in a very few instances, but without an appellate jurisdiction, they possess and exercise the same judicial powers as the lord chancellor. An appeal lies from the decision of the judge to the lord chancellor to the lords justices, and from them to the House or to the lords justices, and from them to the House of Lords.

COURTESY TITLES. (See TITLES.)

COVENANT, kuv'-e-nant, in Theol., is used in a double ignification, the one of which is commonly called the Scriptural, the other the systematic or popular use of the term. In the former sense we find the word repeatedly used in Scripture to denote an arrangement, disposition, or institution, according to which the divine favour is dispensed to those with whom it is made. It is not properly a contract or bargain, which made. It is not properly a contract or bargain, which requires that contracting parties be on an equal footing, and that each has the power of accepting or rejecting the proposals of the other; but it is an appointment or institution by a party infinitely exalted above the other, promising to confer or grant certain blessings in a particular way. God's covenant with man signifies his solemn promise or engagement to or not to do a certain thing. Thus, in his covenant with Noah, he engaged that the waters of the deluge should not again cover the earth. The two greats should not again cover the earth. The two great covenants mentioned in Scripture are what are called the Old and New, or the first and the second; the former of which was that made by God with the children of Israel, when he took them to be a peculiar people unto himself, and is also called the Mossic or Sinai covenant, because it was given to Moses on Mount Sinai. The second, of New Covenant, is that which was instituted by Jesus Christ, and ratified by the shedding of his blood, being the gracious charter or instrument by which God has revealed it to be his pleasure to dispense the sovereign blessings of his mercy to all who will accept of them. As used in a systematic sense, divines speak of two covenants, that of works and that of grace. The former is that which was made with Adam on his creation, in virtue of which be was constituted the federal head of the human race, and his acts became binding on his posterity. covenant of grace is a compact or agreement between God and believers, in which God promises to give them all the blessings of salvation through and for the sake of Jesus Christ; and they on their part voluntarily engage to give themselves to God with a sincero faith. Some divines speak of a third covenant, which they Some divines speak of a third covenant, was ended to call the covenant of redemption, or the engagement entered into between the Father and the Son, by which the Father constituted the Son the representative and Redeemer of the human race, and the Son undertook their redemption.

COVENANT, in the Ecol, Hist. of Scotland, is applied to certain contracts or conventions entered into by the leading Protestants of that country, binding themthe leading Protestants of that country, binding themselves to maintain their religious principles against innovation and opposition. The First Covenant was signed at Edinburgh on the 3rd of Docember, 1557, by the earls of Argyle, Glencairn, and Morton, the lord of Lorn, John Erskine of Dun, and a great number of other distinguished persons. They engaged, with God's grace, to apply their whole power, substance, and very lives, to maintain, act forward, and establish the most bleaged word of God and his congregation. On the 31st of May 1550 arother covenant.

and defend each other against all attacks upon them for the sake of religion. This is known as the Second Covenant, The First National Covenant of Sectland was occasioned by a fear that the young king was too much under the influence of Catholic advisers, and was much under the influence of Catholic advisers, and was signed by James VI., on January 28, 1581, and in it he solemnly abjured the errors of popery. It was afterwards subscribed by the greater part of the no-bility and gentry throughout the kingdom. Attempts on the part of Lennox, Arran, and others of the no-bility, to re-establish bishops roused the country to a renewal of the covenant in 1590; and as the king continued to give indications of a leaning towards prelacy, it was again renewed in 1596. The attempts made by James, after his accession to the English throne, to introduce the episcopal service and forms of worship roused the indignation of the people of Scotland, and the National Covenant was again renewed in 1638. The covenant, as then drawn up, consisted of three parts:—
1. The old covenant of 1581, exactly as at first prepared; 2. the acts of parliament condemning popery and confirming and ratifying the acts of the General Assembly; and, 3. the special application of the whole to present circumstances. The subscribers engaged by oath to maintain religion in the same state in which it existed in 1580, and to reject all innovatious introduced since that time. The subscribing began in the Greyfriars church and churchyard, in Edinburgh, on the 28th of February, and afterwards copies of it were circulated throughout the kingdom, and signed by enremarked throughout the kingdom, and signed by meanly all of competent spe and chiracter. It is worthy of remark that the signing was everywhere regarded set a most sacred act, and some persons of note who offered their subscriptions were refused, because it was supposed that they were influenced more by the fear of men than love to the cause. Those who subscribed were known by the name of Covenanters. Some other this time Charles I some the product of the contraction of the contra after this time Charles I. came to a rupture with the English parliament, and the latter, in order to obtain the assistance of the Scotch, made evertures for a union, which led to the Solemn League and Covenant.
This document was drawn up and ratified by the Convention of Estates in Scotland in 1643, and afterwards accepted and subscribed by the English parliament and Westminster assembly of divines. It bound the united kingdoms to endeavour the preservation of the reformed religion in the Church of Scotland, in doctrine, worship, discipline, and government, and the extin-pation of popery and prelacy and the reformation of religion in the three kingdoms. When Charles II. came over to Scotland, in 1650, he signed both this and the National Covenant before landing, and again on his coronation at Scone, in 1631. On his restoration to the English throne, however, he soon manifested his repugnance to these documents, and they were rescinded by act of parliament in 1661, and burned by the common bangman. After this time, the Covenanters, or those who maintained their adherence to the principles of the National Covenant, in Scotland, were subjected to great persecutions, which served only to confirm them in their principles. Those who refused to abjure the Covenant were regarded as rebels, and were obliged to betake themselves to the desert moors and mountains of their native country, where they were hunted like wild beasts till the establishment of freedom of conscience by the revolution of 1688. sufferings, the courage, and the piety of the Cove-nanters have to this time endeared them to the Scottish mind. Long after the return of more peaceful times, their memory was cherished by the religious with the

faces of the bastion and its salient angle are to the re-entering and estient places of arms. It vered way is an important part of the works of fortress that are constructed beyond the main at a tack on it is attended with difficulty and to the attacking party are easily shot down by a stationed therein as they ascend the glacis; affords the besieged the means of forming with exposure to the fire of the enemy, and deploying for thence in line when making a sortie on the besies from the fortress.

Cow, kow, the female of the bovine species.

Cow, kow, the female of the bovine species.

Cow Bunting (Molathrus pecoris), a passerine
bird of North America. Its most remarkable that
is that, like the cuckoo, it deposits its eggs in strange
nests. It is about the size of the thrush, and is chiefly
black, with a violet tinge. The tail is slightly forked;
legs and claws glossy black, and very muscular.

CowL, or Coul, kowl (Lat. cucullus), is a sort of
hood worn by the Bernardines and Benedictines. They
are of two kinds—the one white and wary large, worn

are of two kinds,—the one white and very large, worn on ceremonial occasions and when assisting at the office; the other black, and worn on ordinary occa-

office; the other Disca, and worn on ormany reservious, in the streets, &c.
Cow-rox. (See Vaccination.)
Cowries, kow-rees, a gen. of univalve shells, remarkable for the brilliancy of their colours, and the high polish of which they are susceptible. They abound bether the all and new world but their greatest the both in the old and new world, but their greatest development, both in point of size and number of species, takes place in warm climates. In the East Indies and many parts of Africa, cowries are used as current coin by the natives.

COYPU, koi'-pu (Myopotarinus Copyus), a redent animal, smaller than the beaver, but of many similar animal, smaller than the beaver, but of many similar characteristics. Its habits are aquatic; it burrows near the margin of rivers, and swims with the greatest case. Its hind feet are webbed; its head large and copressed; cars small and rounded; muzzle long and pointed, and ornamented with bristle-like whiskers, its tail is round, instead of being flattened like the beaver's. It is peculiar to South America, and its skin forms the stanks of a convidently to the forms the staple of a considerable trade.

URAN, krib (Sax. crabba).—This name is popularly applied to the whole of the crustaceaus belonging to the ord. Decapota. This order is divided into three sub-orders,—the Macrara, or lang-tailed crustacea, to which the lobster and crayfish belong; the Anomura, which appears to hold an intermediate position between the former and the third sub-order, the Brachyura. To the latter the common orab belongs. This animal is thus characterized :- The abdomen is always converted into a short jointed tail, quite destitute of terminal appendages, and bent round so as to fold closely under the breast. The cephalo-thorax is usually of a more or less rounded form, generally

broader than long, and often produced in front into a point. The upper surface is entirely covered by a single plate (the cara-pace, or back). The eyes and the inner antenue, the latter of which are very short, can be entirely con-cealed within small cavities of the forehead. The outer antenne are never of any

ORAB.

mind. Long after the return of more peaceful times, their memory was cherished by the religious with the deepest reverence. The sect of the Cameronians still tenniated only by single claws. The feet of the crab, regard themselves as representatives of the old Covenanters. (See Cameronians made by deed, and is in effect a contract entered into by the covenantor with the covenantee. The subject of contracts in general will be found in its proper place, and under the word DEED will be treated the nature and requisites of the instrument by which the covenant is created.

Covenan Way, kur'-erd, a passage round any fortification constructed on the outer edge of the ditch opposite the rampart, and protected from the enemy's fire by the glacis. (See Glacis.) The broad open spaces opposite the angles foreact by the flanks and great length, and the anterior feet are always converted

—baited with meat or some saimal garbage, into which the animal is easily snabled to crawl, but out of which the intellects of the grab are too dull to devise a means of escape. The small edible erab (Camer means) is of secape. The small edible crab (Cancer manas) is also very common on all parts of our coast, but not so much valued as the former. A very curious species is the harmit-crab; belonging to the sub-ord. Anomera. This creature possessing a very soft abdomen, it would be very likely to be seized by some predactions fish, if it were exposed. To prevent this, the hermit-crab seeks for some empty tenement, wherein it may take up its abode. The habitation usually chosen is the shall of some univalve mollusk. Into this spiral home, the hermit-crab is coiled, and retains himself in this position by means of a sucker at the extremity of this position by means of a sucker at the extremity of this tail, assisted by two or three radimentary feet, which are developed upon the abdominal sac; and so firmly does he adhere to his castle, that he will allow himself to be torn to pieces rather than let go his hold. himself to be four to pieces rather than let go his hold.

By protrading his body with its three pairs of legs

from the orifice of the shell, the little hermit is

exactled to walk with ease upon the sandy beach in

exactled to disprey; but the moment danger threatens

him he disprey again into his cell the orifice of him, he disappears again into his cell, the orifice of which is then occupied by one of his claws, which is always larger than the other. As the crab does not possess the same power of adding to the size of the domicile that was enjoyed by the original tenant, he is compelled from time to time to change his residence for one a little larger, and often appears almost as difficult to please as a human householder in the same predicament. Often they may be seen crawling about amongst the empty shells just thrown upon the beach. trying one after another, until they meet with one uniting all the conditions requisite for crustacean comfort; but, until this great object of their search is obtained, always returning to their old house after each unsuccessful trial." Dallas, from whom the above happy description is quoted, says, moreover, that "when two of them happen simultaneously to east a longing eye upon some particular suitable residence, they often engage in a flerce battle for the possession of the coveted object, which the victor always carries of in triumph."

SRA-TALR.

(Gr.), in be-CRAMBE, kramb Bot., a gen, of plants be-longing to the nat. ord. Crucifera. The species C. maritima, or sea-kale, grows wild on the sandy sea-shores of Bri-tain. About the middle of the last century it was first introduced into gardens, and grown like asparagus, under a cover-ing which shielded it from the action of light. In the wild state the plant is very acrid; but, when blanched by the art of the gardener, the stem and leaf-stalks form a delicious vegetable, which is preferred by

CRAFF, bramp (Sax. kramma, Du. kramp), in Med., an involuntary and painful contraction of one or ral of the voluntary muscles connected with a certain part or organ; as of the leg, foot, or arm. It na often the result of cold, is sometimes occasioned by greatly disordered state of the bowels, and frequently openes on without any obvious cause. In general, crains is readily removed by a forcible exertion of the anti-gonist muscles, so as to overcome the spasmodic contraction or by friction and warmth. Cramp of the stomach is to be combated by the external and internal nae of stimulants, and by opium, ether, and other antispasmodics. (See Syrasm.)

Only the best of the cramp a machine read on

the weight is raised to the required height, and, by means of the revolving shaft, deposited anywhezo within the reach of the jib.

Chark, Common (Grus cineres). — This bird is found in considerable flocks in the northern pairs of

found in considerable nous in the nothern pairs of Europe. It measures about five feet in length; general plumage sah-coloured, but forehead black; sides of the head and hind part of the neck white. On the unper part of the neck there is a bare sah-coloured space of about two inches, and above this the skin is naked and red, with a few coloured hairs. The pinion of each wing is furnished with an elegant tuft of curied feathers. The bill is long, straight, and compressed, obtuse to-wards the end, and with the lateral base deeply chan-

nelled. Its nest is usually constructed in some swampy nelical. Its nest is usually constructed in some swampy tract or insulated ruin. It lays two eggs, of a pale dull-greenish colour, blotched with brown. Its food is frogs, snails, grain, vegetables, &c. When a flock congregated on a marsh compose themselves for slumber, some few are navariably wide awake, and stand perched on one leg, looking out for danger. Kolben, with an audseity that should direct particular acrutiny to suything class he may aver, says that these sentinel grames thing else he may aver, says that these sentinel cranes held in the tucked-away foot a large stone, so that should it fall askeep, the falling of the stone would rouse the sleepers. The crane is a bird delighting in rouse the sleepers. The crane is a bird delighting in the wastes that lie on the edges of marshes, or that are subject to periodical overflowings by rivers. Sugh pasturage at one time abounded in England, and then the crane was well known amougst us, and its breeding encouraged, and a penalty enforced for disturbing its encouraged, and a penatry entorest for unsurroung tea-eggs. So long ago, however, as Pennant's time, the bird was regarded as having ceased to exist among us. In proof of the great favour the crane attained in the eyes of gourmands, Pegge relates, in his "Form of Curry," that "William the Conqueror was so exact, Curry," that "William the Conqueror was so exact, so nice and curious in his repust, that when his prime favourite, William Fitz-Osborne, who was daplier or steward of his household, had the charge of the curey, served him with the fiesh of a crane scarcely half rousted, the king was so highly exasperated that he lifted up his fist, and would have struck him, had not Endo, who was appointed steward immediately, after, warded off the blow." The Demoiselle or Numidean canno (Arithmonaliza giran) is a mixing of Afficia. This Carrac (See Oxycoccus.)

Carrac (See Oxycoccus

## Cranicles

#### Crannoges

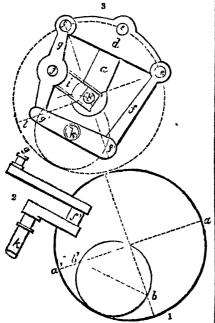

The crowned crans (drdes papersors) is somewhat smaller than the last-mentioned, and is chiefly known by the possession of a close turt of valvely black feathers covering the forepart of the bend, while behind them rises a semarkable overt of fine feathers twisted spirally,

rises a semarkable operator fine feathers twisted suirally, and fringed along its edges with a series of black pointed heirs. Its cheeks and temples are entirely naked, and covered with a bright rocy red.

CLANICLOSY. (See PREENCLOSY.)

CRANTUM. (See BRAIN.)

CRANTUM. (See B or now serva. A new nor rectaines motion of the piston of an ordinary steam-engine by means of a cumecting-rod gives a circular motion to the crank. There are two points in the motion of a crank where the connecting-rod has no power; viz., when the arm of

the grank is parallel with the connecting-rod above or below the axis. In order to carry the crank over these points, the fly-wheel is used. By its impetus the circular motion is kept stondy and regular. The machinery or apparatus termed a connecting-crank, for connecting two shafts so as to cause them to revolve at different velocities, may be illustrated somewhat in the following manner:—We will suppose that the letters ab, in the accompanying figure-present the pitch-line of two wheels, the wheel a being twice the diameter of the wheel b; then for every revolutions of the wheel a, the wheel b will make two revolutions, and if a tracing-point be attached at b', it will describe the straight line a a' upon the face of the larger wheel, and if another tracing-point be attached at the opposite side of the small wheel b, such points will describe straight lines at right angles to one another during the revolution of such wheels. In fig. 1 is shown an elevation of the strangement of levers for connecting two shafts together, so that they may revolve at different velocities. Fig. 2 is a plan of one of the shate, which is provided with a crank forning a portion of the apparatus. In fig. 3, a is a crank fixed upon the end of a shaft (b), supported by suitable bearings; c is the crank-yin which supports the triangular arm d, the grank is parallel with the connecting-rod above or

Cranadoges

through each end of which there are pins (a, a), is the same plane with the aforestid shaft; these pins support two connecting-rode, f, g, the lewer and, of the connecting-rode, f, g, the lewer and, of the connecting-rode of the connecting-rod g being attached to the crank-pin g', of the plan; b is a pin fixed into the end of the sinate, which carries due end of the connecting-link i, the opposite and being attached to the centre or middle of the connecting-link i, the opposite and being attached to the centre or middle of the connecting-link i, the roll pin jr jr in the arm of the shaft, which is to receive motion from the shaft b, or were verifd; consequently, if g be double the length of the connecting-link i, the point g will describe a straight line [I I], and if we suppose g to be attached at its lower end to the crank-pin g', and also the rod f to the orank-pin f', and that the axes b and k revolve in suitable bearings, k will make two revolutions while b makes one revolution.

Channours, kride-nough', a term applied to the lake-

CHANNOGES, krun-ngage', a term applied to the lake-dwellings and fortified islands of the ancient Celts in dweilings and fortified islands of the americal certs in Ireland, Scotland, and other countries. Although dwellings of this kind on Lake Prasias, in Macedonia, were described by Herodotas (book v. chap. 18), the subject did not attract much attention until vestiges of smiler erections were found in other parts of Europe, in 1839, the first orannoge was discovered by Mr. W.R. Wilde, one of the secretaries of the Royal Frish. Academy. After draining the small lake of Lagore, in Academy. After draining the small lake of Lagore, in the county of Meath, a circular mound, which had been an island, was discovered. It was thickly stream with bones, and as these were being removed for manure, the island was found to be of artificial construction. Its diameter was about 140 feet, and it was formed by upright oak piles see an feet long, mortised into oak planks laid upon the sand and mark at the bottom of the water. The piles were united at the top by cross beams, and the space inclosed was divided into compartments filled with bones and black peaty earth. A second tier of piles was also observed raining from the lower tier. The bones were found to be those of horses, assen, oxen, sheep, dogs, &c.; and amounts lower tier. The bones were found to be those of horses, asses, oxon, sheep, dogs, &c.; and amongst them were a large number of swords, knives, spears, cooking-nieusils, and ornaments. Mr. Wilde's discovery was followed by the discovery of several other crannoges in Ireland, some of them perfectly arkifetial, and others partly natural and partly artificial. In nearly all cases, the piles are made of oak, mostly fire young trose from four to nine more above of Theorem. young trees, from four to nine mohes broad. In some crannoges, a causeway leads from the island to the mainland; but they were generally reached by cadors, remuants of which have been found in nearly all. Crannoges are mentioned in the annals of Ireland as sarly noges are mentioned in the annas of treiann as early as the 8th century, and continued to make a figure in history till the 17th century. In the winter of 1883, on account of the continued drought, the Lake of Zurich was unusually low, and the inhabitants of the village of Meilen endeavoured to regain a piece of land from the lake. During the process, the remains of rows of deeply-driven piles were discovered. About the process of the found is the process of the process. them were found a large quantity of weapons, tools, and utenuls of very primitive form and make. On and utenuls of very primitive form and make. On close examination, it was found that the piles had supported a platform, and that the whole building reported a piazione, and that the waste patients re-sembled the crannoges of Ireland. Since that time, thirty to forty crannoges have been found in the upper and lower lakes of Constance, thirty in the Lake of Geneva, and twenty in the Lake of Neufohital. The lake-dwellings of switzerland resemble those described by Herodots more closely than the Celtre crannages.
There is no mention of them in history, but their remains prove that they are ancient. Since 1857, the traces of crannages have been found in nearly every part of Scotland; and remains of lake-dwellings have part of Scottand; and remains of isse-tweinings lawe been discovered in Savoy, Upper Italy, Hanover, Prussis, and Denmark. Traces of a not very certain kind of crunnoge were observed in draining a mere at Wretham Hall, near Thetford, in Norfolk. A learned writer in the Gentleman's Magazine, availing limself of the valuable work on lake-dwellings by the accomplished Swiss archeologist, Dr. Keller, says to "The number of these pile-built settlements discovered, and the attenute examination they have undergone, remove all doubts as to the process of construction. A spot with a sunny aspect seems to have been chosen in some little bay that would in a degree shelter it from the full force of the waves ; and any

those but one with a rocky bottom acreed the purpose. The sate being desided on the marcet trees in the dispent forest were felled for rills. There seems to save been no partiality for any puripolar, word one, she fir, were indispensably taken, even cherry and price stame? It hand; and it is our loss to find in the lasks of Palition that the fir-free has lasted better than be cut. Then exist she process of pointing the piles, which must have been a troublesome business in the laye of slowe axes. It is as yet a matter of regret has so have no systeme as to the way in which the slick disting was performed. We know for certain, exists, that the piles were driven, at a distance of rest case to three hundred feet from the shore, at a highly of six or seven feet, gradually advancing into lease water. They were extended parallel with the have defined in the lake of Geneva, the piles extend twelve hundred feet in life it, by one hundred and streen cabins and the same of six of seven the lates of Geneva, the piles extend twelve hundred feet in life it, by one hundred and twenty in width, giving a manipulate that some three hundred and esteen cabins are also have a population of twelve similar and sixty-four. There is good authority for appearing that the cabins erected upon the pile-superied minifurn were constructed of wattled-work shore but one with a rocky bottom served the purpor sponing that the cabins erected upon the pile-sup-sponing that the cabins erected upon the pile-sup-sponing that the cabins erected of wattled-work stored with clay. The lake-dwelling system must we arisen in the stone age, and endured through the case age, till at least the introduction of iron, and an away in Helvetia. This fact is supported The discovery of several iron swords, about three be long, with blades somewhat over two inches in dib, and iron scabbards, by Colonel Schwab, in the see of Bienne and Neuchatel, which are indisputably of the same type as those recognized as Romano-British and Gallo-Roman—that is, of the late Roman period, when the influence of an alien taste becomes visible in Roman manufactures. How much is known of the every-day life of these ancient dwellers on the Becent discoveries have proved past doubt that the people of the stone age had reached a degree of enture which is not a little astonishing. It was to have been expected that these people should lay in abovered upon them; such as nuts, acorns, beech-man. A surprising fact is the one that they also possessed stores of corn. Professor Heer has found dant examples of a coarse bread, savouring rather mixed corn than mest. It was probably baked on themse, and covered with hot embers. Professor r also found in the same lake-dwelling carbonized or also found in the same lake-dwelling carbonized mins of apples and pears out into halves and stern, and dried in the sun for winter food. The ban holds in Switzerland to the present day, and dried apple-cuttings are sold by measure in the later under the name of senitze. It is certain that a people that flax and hemp, and were acquainted the senitary of measure in the later. the people and flax and hemp, and were acquainted to the means of manufacturing these into fishing.

The great variety of fish-hooks picked up out the lates shows that they knew how to take advanced the rickes afforded by the lakes upon whose text they fixed. They were fully acquainted with art of pottery. They were herdamen likewise, a tentured by the discovery of the remains of oxen, and goats around their old habitations. Consequently, they must have possessed the means of centuring and storing forage for them in winter, or they must have possessed the means of ing and storing forage for them in winter, or asset have perished in the snows, when the healt with difficulty finds subsistence. At channels itself with difficulty finds subsistence. At these lake dwellings everything in fact tells of the gaint, satelled occupation of a primitive race of farmers, hantsens, and finhermen, who in thus establishing their homes above the floods, either adhered to the traditions of their oriental descent, or sought security from their fees. Whether their cattle were also conveyed to the lake-dwelling, as Herodotus tells us of the Pasonians in Lake Frasias, cannot be ascertained. It would seem difficult to conceive how they could have done so without causeways, and these have not generally bean discovered. Probably they were securely parked in at night on the shore, with strong palience, against affacts of beast of prey. Of course likey must have fallen to any invaders strong enough sy must have fallen to any invaders strong enough compel the retreat of their waters to their lake 586

bousse, which in such case, moreover, could hardly have been protected from flery projectics; and in this way, probably, many perished. The archaelogical world is under great obligations to Dr. Relier for his discoveries connected with lake-dwellings—discoveries which take rank only after those of Pompei and Ber-culaneum. The drawing on Plate LAXVIII is bor-rowed from Keller's work on the lake-dwellings of Switzerland.

CEANTARA, or FIREY CROSS, krim tor a (Gaelle, oreun turigh, the cross of shame), was a military signal employed in the Sectish highlands for collecting the distant and scattered clansmen to the standard of the chief. It was a firebrand, or wooden cross, which, after being dipped in the blood of a goat, was sent by a swift-footed nessenger to the nearest hamlet, where he delivered it without uttering a word but the name of the place of rendezvous. The fleetest runner of the haudet was immediately dispatched with it to the next and so on, till all had received notice. It was understood to denounce destruction by fire and sword against all who refused to obey the summons, and was called the Cross of Shame, because disobedience implied infamy. It was in use among the ancient Scandinavisne from whom the Highlanders appear to have borrowed it. The last time this signal was made use of in the Highlands was in 1745.—Ref. Sir Walter Scott's Lady.

of the Lake, canto iii.

CRAPE, kvaip (Fr. orépe), a light transparent silken fabric, from which the whole of the gloss hus been taken in the mode of dressing the eilk. It is soaked in a solution of gum after it has been woven, and dried, which gives it a peculiar shrivelled appearance.

CRASSULACER, krus-su-lai'-se-e (Lat, crassus, thick, CMASSULACE, Frue-su-(ac-se-e) (LBT, crassus, three, from the thickness of its leaves), in Bot, the House-leek or Stonecrop fam., a nat. ord. of dicotyledonous plants in the sub-class Calgoiftora,—succulent herbe or shrubs with exstipulate leaves. The flowers are perfectly symmetrical, the sepuls, petals, and carpels being equal in number (from three to twenty), and the stanger being also camped to them or twice a ware. mens being also equal to them, or twice as many. The petals and stamens are almost, or quite, hypogynous. The corolla is monopetalous or polypetalous. The fruit is either apocarpous and follicular, or a many-celled capsule, with loculicidal dehiscones. The seeds are small; the embryo is in the axis of fleshy albumen. The Crussilveez are found in very dry situations in all parts of the world; a large number occur at the Cape of Good Hope. Astringent, refrigerant, and acrid properties characterize them, and have given a few some importance as medicinal plants. (See Cory-LEDON (the Navelwort) and SEDUM.)

CRATEGUS, krdl-e'-gus, in Bot., a gen. of plants belonging to the nat. ord. Rosacee. The species C. acyacantha is the Hawthorn, Whitethorn, or May, so well known for the beauty and fragrance of its flowers. went known for the ceasity and regrance of its nowers, and for being the best hedge-plant in Europe. Some varieties of this species are highly ornamental, producing double pink or scarlet blossoms.

CHATER, kraiter (Gr. krater, a cup or how), the mouth or orifice of a volcano, so named from its cap.

month of orthogo of a voicence, so minest around the core of bowl shape. (See Volcano.)

Obanyfish, or Chawfish, krail-fish (Astaeus finestills), a crustaceous animal, differing little in general appearance from the lobster. Species of this generate found in almost all parts of the world. The field is reckoned cooling and nutritious. It lives best in rivers, where it takes up its habitation beneath stones and in holes in the banks, there lying is wait for the larve of insects, decomposing animal substances, and amuli fish.

Small lish.

CRAYON, krail-on (Fr. crayon, a pencil; crais, chalk), the name of a pencil of any kind in France, but applied more particularly in this country to pieces of charcost, and black, white, and red chalk, used for drawing on various kinds of tinted paper, and for sketching cartoous, or the outlines of paintings of considerable size on canvas. The best black crayons are made of a soft black earth found in Italy, and the best white suce of a fine kind of French chalk. Crayons are also made by mixing recent the and minaral colouring metals with wide. mixing ege table and mineral colouring matter with pige-olsy or chalk, and giving consistency and adhesiveness to the mass by the addition of a little milk, gom-water, war, or soap. Drawings in orasyon look soft and rich in colouring, but the outline is generally hasy and ill-

defined. A metal tube slit at both ends, which can be compressed at pleasure by a sliding ring, and is called a pertecrayon, is used to hold the chalk; but cometimes the material is unclosed in a casing of wood, and rembles a lead penal; Softnessin shading is produced by rubbing the chalk-marks gently with a piece of leather or paper, which is rolled tightly together and cut to a blunt noint at each end. cut to a blunt point at each end.

ORRAM, kraem (Fr. areme), the oily or butyraceous substance which collects on the surface of milk. When milk is allowed to stand for some time, it undergoes certain changes; the crem, being lighter, rises to the surface, forming a thin layer, while the milk below less rich by the abstraction of the cream, assumes a vale bluish colour, and consists of curd, the substance from which cheese is made. When cream is kept for some days it becomes thicker, and, if suspended in a bien hag in a cool room, will acquire the consist of carried on, the of cheese. Cream cheese is sometimes made in this periods of time. way. Clotted cream is milk and cream in a coagulated and scur state.

CREAK OF TARTAR, in Chem., bitartrate of potash. (See POTASH, BITARTHATE OF.)

tore RUTASH, BITARTHATE OF:
CERROTE, kre'-å sote (Gr. kreae, ficsh; sozo, I preserve), in Chem., a fluid containing oxygen, hydrogen,
and oat bon, first found by Reichenbach, in the heavy
oil obtained by the distillation of wood-tar. It a preparation is too tedious and troublesome to describe
here. When pure, it is a colouriess oily liquid of high here. When pure, it is a colouriess oily liquid of high refractive power, boiling at 308°. It is not easily kindled, but, when burnt, it gives forth a sooty smoky flame. It has a burning taste, and its odour is peculiar. It is sparingly soluble in water, to which it gives its odour and taste. It is free! soluble in acetic acid, alsohol, ether, heard, and tersulplade of carlton. It coogulates albumen immer powerful antiseptic kno stely, and is the most Meat that has been planged into a solution co ring only I per cent. of this substance becomes dry this substance becomes dry and fired on exposure to the air, and does not become putrid. It is thought by many, from its composition and properties, to be a homologue of phenic acid.

CREATINE, OF KREATINE, kre-a-teen' (from Gr. kreas, flesh), in Chem., a substance having basic properties found in flesh and wrine. Flesh contains but a very small portion of this body. It is prepared by chopping up raw cod, mixing it with an equal weight of water, and expressing the liquid. The liquid is then heated, to coagulate the albumon and baryta; water is added as long as it occasions a precipitate. The filtered liquid as mag as to occasions a precipitate. The interest infinite of nearly pure creatine. It crystalizes in colouriess oblique prisms. It is sparingly soluble in cold water and cold alcohol, and insoluble in other. Although neutral to test-papers, it forms definite compounds with some of the acids. By boiling creatine with bydrochloric acid, a new base, -creatinine, is formed.

Cheartnine, or Kreattnine, kre-it-lin'-cen, in Chem., is formed spontaneously in putrid urine, or by acting on creatine with hydrochloric acid, when hydrochlorate of creatinine is formed, from which the acid may be separated by boiling it with hydrated oxide of lead. It requires twelve parts of cold water for solu-tion, but dissolves more readily in hot water and alcohol. Its solution restores the colour of reddened litmus, and it appears to be somewhat strong in its basic properties, forming crystalline sulphates, hydrochlorates, and numerous double salts.

OBBATION, kre-ni-shun (Lat. creatio), in its strict and primary sense, signifies the bringing into being of something which did not before exist. It is therefore generally applied to the original production of the materials out of which the visible world was composed. There is but one underived and self-existing cause by whose power and agency all things were at first created. In a secondary or subordinate sense, it is used to denote those subsequent operations of the Deity upon matter by which the whole system of nature and all the primitive order of things received their forms, qualities, and laws. In this secondary sense, God is said to have created man out of the dust of the earth. The researches of modern elience have raised many questions as to the accuracy of the account given by Moses, in the beginning of Genesis, of the creation of the world, or, at least, of the commonly received inter-

pretation of it. To enter upon the several points of controversy, and to give the various solutions of them, would he to write a book; and this is the less necessary as, to our mind, no estisfactory solution of the difficulties has yet been arrived at. There is indubitable evidence that the world existed many ages, and underwent various changes, before it received its present races of inhabitants, others of other forms and other properties having lived their ages and become stines. The difficult is to reconcile these facts with what we find recorded in the book of Genesis. The most prehable solution, and even that is not without its difficulties, is, that in Genesis we have an account of two distinct or ations, separated from each other by a very long and undetermined period, the first being of the long and undetermined period, the first being in the beginning, when God created the heavens and the earth; the other, when the work of the days was carried on, the days being understood to mean long periods of time. It is to be borne in mind that the great truth which Moses intended to convey to the children of Israel was, that God was the creator of all things; and that it was necessary for him to do this so as to be understood by them, and to conform his instructions to their preconceived or presectived opinions. Scripture was intended to teach theology, not science,—to reveal what could never have been found out by reason, and to leave to reason its own particular province. If, therefore, by the powers of reason man has come to see greater beauties and a sublimer depth in the works of God than have been revealed in his divine word, it seems very unpeasonable to make use of this as an argument against the truth of revelation. To expect from the Bible a scientific account of the works of creation seems as unre sonable as if we were to expect an accurate knowledge of the anatomy of the human body from a child before he attempted to walk. God has given man instincts before reason; and though reason may teach us that instincts sometimes err, these errors cannot be advanced as an argument against the existence of the instincts, but are to be attributed to the imperfections of our nature. God is the author of nature, as well as of the Bible, and, instead of attempting to set up the one in opposition to the other, we ought to wait with patience till some satisfactory solution of the difficulty arrived at. It was an excellent advice of an eminent divine, to learn to "trust God where we cannot trace Him." It is to be regretted that Christians have frequently been led into the error of attempting to establish the truth of Christianity upon a solution of such difficulties as those that occur in the Mossic account of the creation. If in the prophetic writings lengthof the creation. It in the propagate by the term days, ened periods of time are expressed by the term days, the like interpretation may, without any stretch of the imagination, be given to the days of creation, the works of which, though long after the fact, were as much subject of reveision as the other. Science has already furnished us with several very remarkable proofs of the truthfulness of the Mossic account. The order or the truthuness of the Mossic account. The order of creation, as given by Moses, is exactly that which science tells us had been followed. We are told also, that on the first day, God said, "Let there be light; and there was light;" and afterwards we find that the sun and moon were not created or made to shine till the fourth day. This are presented in market the sun and moon were not created or made to shine till the fourth day. This apparently manifest contradiction has been reconciled by modern science, which proves that light exists independently of the sun, and must itself have been an original and independent creation. CREDENCE, kre'-dens, is a small table near the alter

or communion-table, on which the bread and wine to be used in the celebration of the Lord's Supper are placed previous to consecration. They were common in the early churches. The name is said to be derived from the practice in ancient courts of having a sideboard or credence-table, at which the cupbearers and carvers (credentiarii) were required to taste the wines and meats before being presented to the monarch, in case of poison.

CREDENTIALS, kre-den'-shills, are the instruments or letters which an ambassador or other diplomatic minister receives from his own government, to present to that to which he is sent, and which define his powers and show to what rank of minister he is intended to helong. A sovereign has the right to determine the particular character with which he chooses to invest

CRLSSITS.

Cressets were originally surmounted by a small cross. from which cust in they derive their name, and it was by evrying about a fiery cross that armies were raised in Scotland during the clden time. Shakspears makes use of the word in Henry IV.

The front of heaven was full of herry sparks, Of burning cressets

#### Creat

Leaves simple, alternate or clustered, without etipules; flowers irregular, growing out of old branches or steme; calvi free, entire at first, afterwards splitting irregularly; corolla somewhat bilabiate; stames didynamous (two long and two short), with a fifth of a rudimentary character; overy one-celled, and surrounded by an annular diek; fruit indebiscent, woody; seeds large and numerous, without albumen, enveloped in a pulp. The order includes about 38 species, which have been arranged in 11 genera. They are natives exclusively of tropical regions. The sub-said pulp, the fruit of Crescentic Cuyete, the calabash-tree, is eaten by the negroes in Jamsica, and the hard shell is used for holding liquor of sout, and for many other purposes. The fruit of Parmentiara edulis, another plant of this order, is eaten by the Mexicons, and that of P. cerifera is greedily devoured by cattle in Panama. The latter fruit resembles a candle in shape, and the plant is commonly called the candle-tree.

Chest, krest (Lat. crista, a tuit or plume for the helmet), in Her., a portion of the armorial bearings of a nobleman or gentleman entitled to bear coat-armour that is commonly used without the shield, being gainted on the doors of carriages, and engraved on plate and signet-rings. In the days of chivalry the crest or cognizance of the wearer was borne on the helmet. It was made of leather or light wood, gilded and painted, and a wreath of twisted silk was fastened round the lower part, where it was attached to the helmet. In modern times the crest is always drawn on a wreath composed of the principal metal and colour occurring in the bearer's coat of arms, the coils being of metal and colour alternately. Sometimes the crest rests on a cap of maintenance. Crests are supposed to have been introduced into England in the 12th century: they were then used as a means of recognizing the bearer in a tournament. They were generally assumed at the pleasure of the wearer; but there are cases in which crests have been specially granted to families which bear then; among which may be mentioned those of Drake and Hawkins, of Devonshire, the famous admirals of Queen Elizabeth; the former of whom bore a globe surmounted by; a ship, to which a rope was attached, held by a hand, in commemoration of his having circumnavigated the globe; and the latter a negro fettered with golden chains and manacles, for his achievements in the Spanish main.

CREST TILE, in Arch., the name given to tiles running along the ridge of the roof of a building, and surmounted with trefoils, or any other ornament, as a finish. They are chiefly used in Gothic architecture.

CRETACEOUS SYSTEM, kro-tui-she-us (Lat. creta, chalk), in Geol., the name given to the last or uppermost of the secondary formations. As developed in the south of England, it is composed of calcareous, argillaceous, and arennecous rocks, the former predominating in the upper, and the two latter in the lower portion of the system. The strata occurring in England have been arranged into the following groups:

- Upper chalk.—Generally soft white chalk, containing nodules of fint and chert, in more or less regular layers. Lower chalk.—Harder and less white than the upper, and generally with fewer filuts. Chalk marl.—A greyish earthy or yellowish marly chalk, sometimes indurated. Upper greenand.—Beds of silicious sand, occasionally indurated to chalky or cherty sandstone, of a green or greyish white, with nodules of chert. Gault.—A bluish tensicious clay, sometimes marly, with indurated argillaceous concretions and layers of greensand. Lower greenand.—Beds of green or ferruginous sands, with layers of chert and indurated sandstones, local heds of gault, rocks of green or chalky limestone (Kentish rag), and fuller's earth. A more comprehensive classification, derived from the study of continental as well as English strata, is given below, with the estimated thickness of each subdivision:—

Maestricht and Faxoe bods	100 feet
Titlier aboth with Hinte	500
White chalk without flints	600
Chalk marl	100
Upper greensand	100
Gault	150
589	1946 Burney

#### Cretinism

There is no place where all the above strata are present at once, and some are very local and inconstant. The Wealden beds, so called from their forming district knows as the Weald of Kent and Susser, have only recently been included in the oretaceous systems. They consist of sandstones and shales, with a few beds of limestone and ironstone, and, as developed in the south-east of England, they seem to occupy the size of an ancient estuary which received the clay and mud of some gigantic river, whose waters occasionally bore down the spoils of land plants and land animals, to be entombed along with those of equatic origin. The life of the whole oretaceous period was abundant, as the known fossils within the British area represent land plants, fresh-water and marine shells and flah, large terrestrial and marine reptiles, and species of every class of animal having hard parts capable of preservation, except birds and mammals; and even as regards these, most geologists believe their absence to be accidental, as both existed during the preceding period, though their fossil remains are very rare. The more important useful products of this system are chalk, flint, fuller's carth, phosphatic nodules, and the so-called "firestone rock." The two latter are extensively employed as manures.

sively employed as manures. CRETYMEN, krei-lin-tem, is idiocy arising from im-perfect formation or development of the brain, and generally accompanied with great bodily deformity. The name is of uncertain origin. Some derive it from The name is of uncertain origin. Some desires, a low Chreiter (Fr., a Christian), because they were generally regarded as beings incapable of sinning, and thus were viewed with some kind of respect. According to others, it is from the Romance, or Grison evening, a corruption of the Latin creatura, a creature. These unfortunate beings are chiefly to be met with in the valleys of the Alps, particularly in the Swiss cantons of Valais, Vaud, Grisons, Glarus, Uri, and Aargan; but they are by no means confined to these parts, being much more extensively spread than was at one time supposed. Cretinism is often accompanied with goitre (which see). There are various degrees of Cretins: some seem to be sunk in intelligence below the level some seem to be sunt in meangence below the leves of many of the brutes; while others are able to go about and attend to some easy labour. The Cretin seldom attains more than 4½ feet in height. The cranium is deformed, and has a conical shape, the forehead being thrown backwards, narrowed, and flattened, and the occiput being nearly on a line with the neck. Their eyes are small, the nose broad and flat, the mouth large and open, with the tongue often protruded, and the whole countenance is idiotic, or expressive only of lasciviousness. The flesh is soft expressive only of lasciviousness. The ness is soft and flaccid; the skin writikled, yellowish, or pale and cadaverous; the belly large and pendulous; the limbs crooked, short, distorted; and the gait imperfect and waddling. The cause of this infirmity is still matter of dispute among physicians. Some attribute it to the nature of the water by which an under account on dispute nuonic physicians. Some attribute it to the nature of the water, by which an undue amount of calcareous matter is conveyed into the system; others to the stagnation of the atmosphere in the deep nargow to the stagnation of the atmosphere in the deep narrow salleys. There are other causes that may possibly exert an influence upon it; as the poor diet and filthy, lazy, and intemperate habits of the people among whom it exists, together with the intermarriages among near relatives. There can be no doubt that it is in some measure hereditary, though all the children of a family are not affected by it. Many attempts have recently been made to improve the condition of the Cretin. The first thing to be done as soon as the disease manifests itself (for in many cassa it does not appear till some itself (for in many cases it does not appear till some time after birth,—sometimes not before the sixth or time after birth,—sometimes not before the sixth or seventh year) is to remove the sufferer to a pure bracing atmosphere. The treatment required is first to get the body into a healthy condition, by simple and nourishing food, warm clothing, frequent bathing and friction of skin, and gentle exercise. The development of the mind will follow that of the body, but must be done very gradually. Dr. Guggenbühl was the first that made any systematic attempt to educate the Cretin. He opened his institution on the Abendberg, in the

canton of Bern, Switzerland, in 1840; and since that time several other institutions for the same purpose have been established on the continent.

CREW, kreu (a contraction of Sax. cread, or cruth, a Curw, kees (a contraction of Sax. cread, or cruth, a crowd), in Mar., the company of sailors belonging to a ship, boat, or other vessel. In an English vessel of war the entire crew are thus arranged in groups:

1. Warrant and subordinate officers; 2. chief petty officers; 3. working petty officers of the first class; 5. comprehends all those lower in rank than the fourth class. A chief seronany or crew is also subdivided into see prehends all those lower in rank than the fourth class.

A ship's company or crew is also subdivided into several minor groups,—the hoatswain's crew, the gunner's crew, the sail-maker's crew, &c.

CRIBBROF, krib'-bij (Ang.-Sax.), a game played by two persons with a complete pack of fifty-two playing-cards. It is divided into two classes, the five-card

and the six-card games. The five-card is the original game, and affords the greatest scope for the exercise of skill. The points are scored upon a board, and sixty-one points constitute the game. All the kings, queens, knaves, and tens, count as ten each, and the rest of the cards according to their ordinary value; that is, six for six, five for five, and so on. The points which reckon for the game are fifteens, sequences, flushes, pairs, &c. After dealing, the players gather up their cards, and having taken out two each, place them, with their faces down, on the table. These four cards form the "crib," which becomes the property of These four the dealer, under certain conditions. Points are scored in two different ways in cribbage,-first in play, and an two concrete ways in cribbage,—nest in play, and second in reckoning up the cards held. After the crib is put out, the pack is cut by the non-dealer, and a card turned up by the dealer. When this card is a knave, it is called "two for his heels," and counts two to the dealer; and a knave held in hand, of the same suit as the turn-up card, entitles the player to score one; it is called "one for his nob." Six-card cribbage is played called "one for his Bob." Six-card cribbage is played in a very similar manner, but is inferior in science to five-card cribbage. When three parties play at the game, each plays on his own account; and when four play, sides are generally chosen. (For rules, &c., sce Bohn's Handbook of Games.)

Bohn's Handbook of Games.)

! Carcurar, kvik'-et (Du. krekel).—This well-known little insect has been, and is still, a subject of much delusion. Notwithstanding that modern naturalists have cleared up all mystery connected with the cricket, if ever any existed but in the rude and untangbt mind, still, at the present day, there is many a household in England any member of which would be consistent that chirms of the cirket with some fatality. associate the chirping of the cricket with some fatality, and consider it an alarming omen. Thanks, however, to the variety of superstition, by many persons it is considered as a sign of good luck, although with about as much reason as in the former notion. At any rate, it possesses the merit of being a less harmful superstition, and may, without much injury, remain, until a purer and truer knowledge shall dawn in the dark corners that are still untouched with the blaze of Processes. The cause of the obliging noise made by the gress. The cause of the chirping noise made by the cricket, and which is so familiar to the fireside listener during the cold winter evenings, is simply the friction of the wing-covers against each other. The house-cricket is about an inch in length, and the antenne often half again as long as the whole body. It is found in various parts of Europe, more particularly in the south. In Great Britain it is very abundant. Only in the sinter months does the cricket take up its abode with man, usually selecting rooms on the lower floor, and greatly affecting the kitchen, where there is gene-rally as lack of food lying about. Sometimes it selects chings and crevices in which to hide, and often burrows in the mertar, where, through the long evenings, it chirps continuously. Its monotonous chant is conchirps continuously. Its monotonous chant is considered very amusing by some; by others, whose temperaments are of a nervous nature, it is thought to be disagreeable and irritating. In the summer, the cricket takes its departure, and finds an abode in the crevices takes its departure, and finds an abode in the crevices of garden-walls and such-like places. At this season it does not forget its melody but it is said, in the fine summer evenings, to chirp more pertinactously. The deld-cricket is also found in this country, but is not nearly so common as the preceding species. It is exceedingly reserved in the labits, avoids the society of man, and prefers hot, and y localities; it burrows in

#### Cricket

the ground, and there lies all the year round. field-cricket is carnivorous, and preys upon other in-sects. It is larger than the common species, and its chirp is much louder. Another interesting species is the mole-cricket, whose habits are very singular, and greatly resemble those of the animal from which it is named. In its structure, too, there is a remarkable named. In its structure, too, there is a remarkable similarity. This insect is continually engaged in excavating galleries under the earth, some of which are of considerable dimensions. To enable it to do this with perfection, its anterior limbs are connected into

CRICKET.

a pair of flat fossorial organs, which are in appearance much like the hand of the mole. In its burrowing processes, it does great injury to the roots of plants. With regard to its diet, little is positively known; and whether it lives on vegetable or animal food, is still a matter of uncertainty. By some authorities, however, it is said to feed on both roots and insects. The female of this species prepares a large chamber wherein to lay her eggs, which are said to be from two to four hundred her eggs, which are said to be from two to four hundred in number. Until after the first moult, the young remain together, but then take their departure, and commence burrowing on their own account. The mole-cricket is usually about two inches in length, and is of a brown colour. The most extraordinary cricket is that found in Sieily (Grythes megacephalus), which chirps sufficiently loud, it is said, to be heard distinctly to a wild distant (1). at a mile distant (!).

CRICKET (Sax. cryce. a stick), a well-known national English game, played upon a level piece of turf, generally about one or two acres in extent. In a full game of cricket, there are eleven players on each side; and two bats, a ball, and two sets of wickets, with bails, are required. There must also be two umpires and two required. There must also be two umpires and two scorers. Although an ordinary game is usually played with eleven on each side, there is no restriction as to numbers; the parties may stipulate for eleven against twenty-two, twelve against twenty, &c. When a game is about to be played, the wickets or stumps are placed opposite to each other, three on either side, at a distance of twenty-two yards. Each wicket is twenty-seven inches in height above ground, and the three are connected at the top by two loose bails, four inches long each. Two lines are then drawn upon the grass at either end. The first is in a line with the stumps, and is called the "bowling-crease;" the other is parallel, four feet in front of the wicket, and is called the "popping-crease." Having chosen sides and tossed for innings, the players on the side which is out take their places. The bowler places himself behind the wicket from which he intends to bowl, and the wicket from the contract of the wicket of the creaty behind the wicket opposite to him. is about to be played, the wickets or stumps are placed keeper directly behind the wicket opposite to him. The rest of the men on the outside are called fielders, and consist of the long-stop, point, cover-point, short-slip, long-slip, middle-wicket, long-field off, long-field on, and leg. All being arranged in their places, the players on the inside send out two batsmen, who take up their posts before each wicket respectively. One of the unpires then calls "play!" and the bowless delivers the ball towards the opposite batsman, his object being either to hit the wickets or to bowl it in such a way that the batsman may play a catch. In either of these cases the striker is out. But if the batsman can hit away the ball to such a distance that

Crima

Crocket

he is able to exchange places with the opposite bats-man, he scores one run to his side. Every time an man, he scores one unito his side. Every time an exchange of places safely occurs, a run is scored to the side who has the innings. The delivery of every four balls constitutes an "over," when the bowling is transferred to the opposite wicket, and all the fielders change their positions accordingly. When a batsman is put out, another of the players on his side takes his place, and so on, till all the players but one are put out, when those who have had their innings field out and those who have hear fleiding out take their innings. Each blave been fielding out take their innings. Each wao nave been neuting out take their innings. Each side has two innings, and the party that makes the largest score wins the game. There are several stringent laws with regard to the bowling. If the bowler sends a ball on the outside of the "popping-crease" at the opposite wicket, it is called a "wide ball," and scores one to the justide. The bowler must blee delivers scores one to the inside. The bowler must also deliver the ball with one foot behind the "bowling-crease;" the ball must be bowled, and not thrown or jerked and the howler must not raise his hand or arm above his shoulder in delivering the ball. An infraction of these rules constitutes a "no ball," which scores one to the inside. There are many other laws of cricket, which have lately been revised. (See The Cricket-bat, and How to Use it,—Baily Brothers, Cornhill: 1861; Felix On the But; and Lillywhite's Guide to Cricketers.) Though comparatively modern in its origin, cricket seems to have taken the precedence of all other national games. Nearly every town, village, and school, possesses its cricket-ground; and cricketers are to be found in all classes of the community, from peers to peasants. Military authorities hold the game in such high estimation, that soldiers are encouraged to play at it in their leisure. No game tends more to the development of muscular strength and activity then cricket. Many professional men in England make their living by playing matches. The Maryle-bone and the Surrey clubs are the most influential, and the "Eleven of all England" and the "United Eleven" are the two finest cricket-clubs in existence. In 1859, a number of cricketers went from England to America and played a number of matches, on account of a challenge which came from the latter country; and in 1860-61, another body went to Australia, where they played many games. In both cases success attended the cricketers who came from the Old country.

CRIME, krime (Lat. crimen, Fr. crime), is the violation of a right when considered in reference to the evil tendency of such violation as regards the community at large, although it may be a civil injury if considered in relation to the damage which the party who is made the subject of it individually sustains. The distinction of public wrongs from private, -of crimes from eight injuries, seems, upon examination, to consist in this,—that private wrongs, or civil injuries, are an infringement or privation of the civil rights which belong to individuals, considered merely as individuals. Public wrongs, or crimes, and misdemeanours, are a violation of the same rights, considered in reference to their effect on the community in its aggregate capacity; and, thus understood, they are classed either as

folionies or misdemeanours (which see).

ORIMINAL LAW. (See LAW.)

CRINOIDEA, kri-noid's-ä (Gr. krinon, lily: eidos, likeness), an exteusive order of animals, chiefly fossil, belonging to the class Echinodermata, and so named from their lily-like appearance. In existing sens, the crinoids are represented by the Comatulæ, or featherstars of our own shores, and by the rare and all but extinct Pentacrinites of the West Indies. The comatula, though free-floating in its adult state, is attached by a stalk to the sea-bottom when young; attached by a stalk to the sea-bottom when young; the Marsupite, a fossil form, appears also to have been free in its mature state; but every other crinoid was provided with a long, slender, many-jointed stem, by which it was fixed, during life, to the roes. The characteristics of the order, which is of wast goological interest, are well exemplified in the Pertacrinus. This animal may be described as a stalked covactule. The stalk, which is composed of calcareous joints or ossicles articulated to each other by radiated authorize a contract a variety of recentsful are un formed. surfaces, supports a vasiform receptacle or cup formed of five calcareous plates, and in this receptacle the digestive and other viscers are situated. The upper part of the receptacle is covered by a plated integra-

ment, in which there is an aperture for the mouth. From the brim of the oup proceed ten many rayed area, farnished with articulated feelers or pinnes captale of expansion and contraction, for the captale of prey. The principal fossil families are described under the head of ENCRIBITS.

CENTOLINE, krin'-o-leen (Lat. crinis, hair), a stiff fabric formerly made of horse-hair, and used in order to distend female apparel. The term originated among the Parisian milliners, and at first was only applied to this particular kind of hair-cloth; but it is now applied to every kind of hoop by which women's dresses are expanded. The hoop or crinoline, as now now applied to every kind of hoop by which women's dresses are expanded. The hoop or crinoline, as now generally worn, is made of various materials; such as cane, whalebone, steel wire, &c. Some are made of very extensive size, reaching a circumference of even five yards. The hoop came into fashion about 1856, and has remained in vogue ever since. The habit of wearing hoops is not new, as they formed an article of attire in the reign of Elizabeth: they were then called furdingales. They went out of fashion in James I's reign that came in again in 1711, and for James I.'s reign; but came in again in 1711, and mained in fashion till the reign of George IV

mained in fashion till the reign of George IV. They were then only worn by the courtiers; their use had been given up in private life. The king abolished their use in court at last by royal command.

CRISIS, kri'-sis (Gr. krino, I decide), in Med., denotes the decisive period or event of a disease,—a sudden and considerable change of any kind, occurring in the course of its progress, and producing an influence upon its character. Among a releast plusidings it was upon its character. Among ancient physicians, it was applied to that tendency which fevers were supposed to possess, of undergoing a sudden change at particular periods of their progress. Hence there were what were called critical days,—certain days in the progress of an acute disease on which a sudden change, either favourable or unfavourable, would take place. seventh, fourteenth, and twentieth or twenty-first days, were regarded as eminently critical. Little importance is now attached by medical men to critical days.

CRITIMUM, krith'-mum, in Bot., a gen. of umbelli-ferous plants. The species C. maritimum is the sam-phire, which is commonly used as an ingredient in mixed pickles. It is found growing on the seashore, and occasionally on old walls.

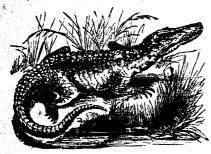

CRITICISM, krif'-e-sizm, has been defined to be "the art of judging with propriety concerning any object or combination of objects." In a less extended sense, it is the application of the principles of taste to matters connected with literature and the fine arts. The obconnected with interactive and the fine ares. The object which it proposes is to distinguish what is beautiful and what is faulty in every performance; from particular instances to ascend to general principles, and so to form rules or conclusions concerning the several kinds of beauty in works of genius. It lays down those forms or ideas which answer to our con-ception of the beautiful, and points out, by reference to these, the excellencies or defects of individual works. The rules of criticism are not formed by any induction à priori,—that is, they are not formed by a train of abstract reasoning independent of facts and observations. Criticism is an art founded wholly on experience, founded on the observation of such beau-ties as have been found to please mankind most generally. Such observations, taking their rise at first from feeling and experience, were found upon examination to be so consonant to reason and the principles of human nature, as to pass into established rules, and to be applied for judging of the excellency of any performance. In a still more limited sense, criticisms is applied to a particular branch of literature. To this branch belong essays or articles in magazines, reviews, &c., upon particular books, pointing out their various merits and defects.

CRITIQUE, or CRITIC, krit-eek', krit'-ik, in Phil., is a term adopted from the Germans, and is applied to the science of the pure faculty of reason, or the investiga-tion of that which reason is able to know or effect ton of that which reason is able to know or effect independently of experience. It is applied to the philosophical system of Kant, from his famous work entitled the "Kritik der reinen Vernunft" (Criticism of Pure Reason). (See Kantlan Philosophia, Crocket, krok'-et (Fr. crocket), in Goth. Arch., an ornamental projection on the edges of the sides of pinnacles, canopies, spires, &c., consisting chiefly of

# Crocodile Family

leaves and knots of foliage, and occasionally of animals. They were small and insignificant when they were first introduced; but they became larger and bolder in the Decorated and Ferpendicular English styles.

Caccorns Family, krok-o-dile (Gr. krokodeilos), the largest order of the Saurian order of reptiles. The tail is flattened at the sides; there are five anterior and four posterior toes, of which the three inner ones only on each foot are armed with claws; all the toes are more or less joined by membranes. There is a single row of pointed teeth in each jaw; and the tongue is fleshy, flat, and attached very nearly up to the edges, which led to the ancient belief that the erocodile was without a tongue. The back and tail are evered with large and strong square scales, elevated into a ridge on their middle. There is a deeply dentionated crest on the tail, at the base of which the crest becomes double. The scales of the belly are against delicate, and smooth. The noistrils are opened at the end of the muzzle by two small crescent-shaped alits, closed by small valves, and lead, by a long and straight canal pierced in the palatine and sphenoidal bones, to the bottom of the back part of the mouth.

CROCODILE.

As the lower jaw is prolonged behind the skull, the upper jaw has the appearance of mobility, but it only moves in concert with the whole of the head. The external ear is shut at will by two fleshy lips. The eye has three lids. Under the throat are two small glanhas three lids. Under the throat are two small glandular orifices, whence issue a musky secretion. Like the rest of the Lacertæ, crocodiles are oviparous. Their eggs are deposited in the sand or mud on the banks of the rivers they frequent; and the young, when hatched, immediately proceed to the water. The egg of the crocodile is not much larger than that of the goose; but it is very much harder, and its form more oblong. As is the case with many newly-born creatures, the head of the young crocodile seems monstrously large as compared with the rest of its body. "The laying of the eggs," says M. Ricord, "takes place in April, and the number amounts to from twenty to twenty-five, more or less, laid at many times. The to twenty-five, more or less, laid at many times. The semale deposits them in the sand with little care, and scarcely overs them. I have met with them in the lame which the masons have left on the banks of the river. If I have reckoned right, the young ones come forth on the fortieth day, when the weather is not too cold. At their birth they are five or six inches in length. They are hatched alone; and, as they can do without nourishment while coming out of the egg, the female is in no hurry to bring it to them. She leads them towards the water and into the mud, and disgorges for them half-digested food. The male takes no account of them." In crocodiles the number of teeth does not vary with age, as in other animals, the teeth being hollowed at the base in such a manuer as to serve for the case or sheath of the germ of the tooth serve for the case or sheath of the germ of the toomerous, large, and of unequal length. Chvier says that the crocodile cannot swalkow while in the water, but that it first drowns its prey and places it in some nook under water, where it is allowed to putterly before it is eaten. This is denied by certain modern travellers and natu-

#### Cross

favour of Cuvier's opinion. The prey of the oregodile is chiefly fish, but it derives a considerable part of its suste-nance by lying in wait in the evening at the water's edge. hance by tyling into the water any amail quadrujed may come to drink. They have been killed in Egypt exceeding thirty feet in length. Its colone, a full grown, is blackish brown slove and yellowish. nun grown, is mackish brown above and yellowish white beneath; the upper parts of the legs and the sides are varied with deep yellow, and parts of the body bear a green tinge. No living specimen of this family is found in Europe, nor has any at present been disco-vered in Australia. Africa is the native country of the crocodile, and it is also found in Madagascar. The crocodiles are generally considered as forming a natural passage from the saurians to the chelonians, to the last genera of which, in certain points of their conformation and habits, they nearly approximate. The Crocodilida are divided into two great families,—the crocodiles proper, which are distributed in the Old and New world, and the alligators, which are peculiar to world, a.

CROCUS, kro'-kus (Gr. krokos), in Bot., a gen. of plants belonging to the nat. ord. Iridacea. From the species C. vermus and versicolor numerous varieties have been produced by cultivation, which are of great value in the flower-garden, on account of the early appearance and remarkable brilliancy of their flowers. sativa is the saffron crocus, the karcorn of the Bible. C. satted is the sauron crocus, the karcorn of the Bible. The dried stigmas of this plant, with the top of the style, constitute kay-soffron, or, when pressed together, cake-suffron. The latter is seldom met with in the shops, the product sold for it being simply the pressed florets of the saflower. (See Carinamus.) Saffron is much used as a flavouring agent on the continent and in the East. In Britain, it is principally employed as a colouring agent in pharmacy, and medicinally in certain nervous affections, and as an emmenagogue.

CROMERCH. (See CELTICA ARCHITECTURE.)
CROP, krop (Ang.-Sex.), a term applied to the quantity of corn, roots, grass, &c., grown on a piece of laud at one time. The order in which different crops are made to succeed each other was not made a subject of scientific research till the middle of last century.

CROSIER, kro'-zhur (from the root of cross), the crook or pastoral staff of a bishop, the emblem of pastoral authority and care. Strictly speaking, the crosier is a staff surmounted by a cross, although it is generally confounded with the pastoral staff, which is made in the form of a crook. The use of crosiers is very ancient. The Byzantine crosier had at the top eithera cross or a knob, with curved When the serpents on both sides. bishops pronounce solemn benediction, they take this emblem into their hands. These staves were sometimes barely curled, and sometimes were highly ornamented and enriched with costly jewels. One of the most costly crosiers remaining in England is that of William of Wykeham, of silver gilt, richly enamelled. It is exhibited to visitors in the chapel of New College, in Oxford, to the so-ciety of which the bishop presented it in 1404. Another fine crosser is that of Bishop Fox, preserved at Corpus Christi College, Oxford.

Cross, kros (Lat. crux), a common instrument of capital punishment among the ancients. It was made of two pieces of wood, crossed either at right angles or otherwise, on which the bodies of the malefactors were fastened, and left exposed till death put an end to their sufferings. After the crucifixion of Christ, the cross became the emblem of the Christian religion. Constantine, believing that he had guined his victory over Maxentius through the sign of the cross, caused them to be set up in public places and upon public buildings. caunot swallow while in the water, but that it first drowns its prey and places it in some nook under water, where it is allowed to putrefy before it is eaten.

This is denied by certain modern travellers and naturalists, but many reliable authorities quote instances in nished to find that the natives used the cross as a religious symbol in their temples. Early in the Christian dispensation, however, the cross became an entlem of the religion. The large cross over the entrance to the chancel of a church was called the Rood, or Holy Rood, and became an object of veneration. The rood was often elaborately ornamented. Crosses are of various forms: in the Latin cross, the horizontal

CROSSES

bar crosses the perpendicular near the top, while, in the Greek cross, which is similar to the cross of St George, the horizontal crosses the perpendicular in the centre. In the cross of St Andrew, the two bars the centre In the cross of St Andrew, the two bars cross each other diagonally After the union of Scotland with England, the cross of St George and that of St Andrew were blended, forming the union jack. The St Andrew were blinded, forming the union jack. The Malties cross is merely the Greek cross, with an orns mental expansion of the ends. Monumental crosses were often raised (tiber to mark a boundary or the enfrance to a sanctuary. Many striking remains of these crosses are to be found in Great Britain and Related Monumental crosses are reserved by Edward Company of the crosses are to be found in Great Britain and relund Monumental crosses were erected by Fdward I on the places where the body of Queen Eleanor rested while being borne to buttal at Westminster The crosses of Charing, Cheapside, and Waltham, belonged to these. The two forms have disappeared. belonged to these. The two forms have disappened, but the latter still remains. Market or town crosses were originally stands from which the celesiastics preached. St Paul's cross was one of the most famous of these. It was situated near the present sit of St Paul's Cathedral, and was a sentially a place of preach and for the town. It was, in the latter days, in the form raus scatterars, and was e sentially a place of picach ang for the town. It was, in its latter days, in the form of a plain pulpit, made of wood, and was surmounted by a Maitese cross. Round it were arranged seats for the audience. It was displeasing to the Puritans, and was demolished by order of the parliament. Nearly every old town in England has either a town cross or the seminant of one. the remains of one

CROSS, VICTORIA, a reward which may be granted cases, victoria, a reward which may be grunted to a soldier of any rank to mail any act of valour. It was first justified in 15 6, at the conclusion of the Crimean war. It is in the form of a Malless cross, and is composed of metal taken from the Russian guns capture 1 at Schastopol. In the centre of the cross is the royal crown surmount d by a hon, and on a scroll below is the legend, "For Valour" On the clasp below is the legend, For valour. On the classy two branches of laurel are represented, and the cross hangs from it supported by the letter V. peint of the upper, but not beyond it towards the left side, while on its own side the point passed with ease to a distance of three-eighths of an inch. The upper mandible has a limited degree of motion on the cramandote has a limited degree of monous on answering num, the superior maxillary and masal bones being united to the frontal by a flexible bony lamina. "

(Yarrell) The chief colour of the crossbill's plumage is ashy-rrey, with a greenish inge on the upper parts, while the lower parts are yellowish green. Its bill is born-colour, its length about six inches. This is the plumage of the adult bird, after the first moult, howplantage of the state of a terr to earst mouth, now-ever, and until the bird is a year old, all its upper and lower parts are of a tarmshed red, more or less tinged with green and yellow, while the lower coverts of the tail are white, with a brown spot in the centre.

tail are white, with a brown spot in the centre.

Choss Buns, a small spiced cake, narked with a cross, and specially prepared for Good Friday. The hot-cross-bun is the most popular symbol of the Roman Catholic religion in Figliand that the Reformation has left, they are supposed to represent the eulogies, or consecrated loaves, given sway as alms to those who, from any impediment, could not receive the host. They were madded with a cross similar to that on the Good Friday hun.

Good Friday bun

CROYALISIA, kro-tā lav-re-ā (Gr krotulon, castanet; on account of the rattling of the seeds in their inflated nods, when shaken), in Bot, a gen of plants belonging to the nat ord Leguminose, sub-ord Positioneese. C' nunca, an Indian plant, furnishes a coarse fibre cilled ann, sinn shansm, taaq, or Bengal kemp, when is often confounded with vanue, the fibre of the Histories cannabinus C. tenuifolia, another Indian species, is the source of the Jubhulpore hemp

the source of the submittees army
CROTAIUS (See RATTLE SNAKE)
CROTCHET, kroth'et (Fr crochet), the third principal
note in music It is equal in duration to half a minim,
or the fourth of a semily eve

CROTON, kro'-ton (G1 kroton, the dog-tiek, in reference to the resemblance of the seeds to that vermin), in Bot, a gen of plants belonging to the nat. ord. Emphorbacea. The seeds of the species C. Tulium, and probably also those of C. Parana, constitute the croton, ortigium also those of C Parana, constitute the croton, ortifician seeds, of the materia medica. They yield, by expression, an oil called croton oil, which, in doses of from one to three mains, is a powerful drastic cathartic, and, when applied externally, acts as a rubefacient and counter irritant. The seeds are used without preparation, in India, as purgative pills. C Electric and Cascarilla, natives of the Bahama islands and Jamaica, yield the aromatic tome bark commonly known as case irilla or eleutheria bark. C pseudo China violds the coulled conglish hards of Peraira, and C wither yields the quilled copaiche bark of Pereira, and C suberosum the corky copaiche bark of the same author. In their medicinal properties the copalche banks resemble cascar lia The aromatic bark known as Malambo bark is the produce of C Malambo It in extensively used in Columbia as a remedy in diarrhera and as a vermifuge, also externally, in the form of an alcoholic tincture, in rheumatism

CROUP, kroop (Ang. Nor), in Med, is an scute in-flammation of the mucous membrane of the larynx, but frequently extending also to the traches and bronches tubes. This disease is not mentioned by medical writers before the middle of last century, and it is the writers before the middle of last century, and at us no epimon of many that stid do not exist prior to that time. It is a disease that is very prevalent and fatal among infants. It is usually preceded by the symptoms of a common cold, with hoarseness and a haran cough, pain in the head, fever, and swelling and redness in the back of the throat, but if may make its appearance suddenly during the night, in the midst of apparent health. In a short time the respiration becomes noisy and difficult, accompanied by a growing sound during. occurs after the age of publicty, though occasionally it is to be met with among adults. It is most comman in cold damp seasons and in low marshy localities. In so rapid and fatal a disease, medical advice ought to so rapus was natus a cusease, medical advice ought to-be immediately obtained. Biseeding, except by leeches, is not now generally approved of by medical men: some recommend emetics and purgatives; others optum and calorael. Warm bathing, or spouging with warm water, should be had recourse to, as well as the inhalation of a water water. the inhalation of a watery vapour.

CROW, COMMON, OF CARRION, kro (Sax. crave) (Cor-cus Corone).—This common British bird is, perhaps, as well known, and at the same time as little liked, as any festbered creature. The farmer hates him for his appetite; the rural inhabitants hate him because so does the farmer; and, on account of his sombre attire, connected with the agricultural interest are seldom squeezish about the fate of a crow, nor upt to regard as siight but a justly-punished criminal the wide-spread and gibbeted carcass of poor corvus set out, as in a pea-field, as a warning to its reliets. Only it happens that the crow is gifted with an extraordinary amount of intelligence, he would, erc this, have been banished from the face of the land. The carrion crow is spread over the Old and New continents, and feeds, like the ravens, on any sort of animal offul, or, when this is not worms, moles, mice, caterpillars, grubs, beetles, &c. In the winter it associates with the rooks, and may be seen with them busily turning over the earth in search of food. The nest, like that of the rook, is constructed at the summit of a tree of slender branches, matted with clay and horsedung. The hen lays four or five eggs of a palish green, sometimes blurred and spotted with a darker colour. They lay but roce in the year, unless the young or the eggs he destroyed by accident. It is said that the crow may be domesticated, and taught to speak as distinctly as the raven. "The carrion crow will feed yoracionsly on ripe cherries; and in the autumn he will be seen in the walnut-trees, carrying off from time to time a few of the nuts. With the exception of these two petty of the nuts. With the exception of these two petty acts of depredation, he does very little injury to man during nine or ten months of the year; and if in this period he is to be called over the coals for occasionally throttling an unprotected leveret or a stray partridge, he may fairly meet the accusation by a set-off in his account of millions of noxious insects destroyed by him. However, in the spring of the year, when he has a nest full of young ones to provide for, and when these young begin to give him broad hints that their stomachs would like something of a more solid and substantial nature than mere worms and caterpillars, his attention to game is enough to alarm the atoutest-hearted squire or henwife. These personages have long sworn as eternal enmity to him, and he now, in his turn, visits, to their sorrow, the rising hopes of the manor with ominous aspect; and he assaults the broods of the duck-pond in revenge, as it were, for the many attempts both squire and henwife have made to rob and strangle him."—(Waterton.) The hooded crow Corne Corner) is rather smaller than the preceding, with black head, throat, wings, and tail. Its name is derived from the contrasted black head and grey body. It is more ferocious than the carrion crow, and has heen known to pick out the eyes of lambs, and even of horses helplessly hampered in bogs. In certain parts of the Farce Islands it is no uncommon thing for these birds to assemble in great force, say a thousand in number, and, while the rest appear to sit wrapped in the profoundest attention, one or another will flutter the profoundest attention, one or another will flutter his wings and "caw" at a tremendous rate. When he has done another begins; and so the meeting continues for an inclusion so. Then they break up, and it is not uncommon to find one or two birds left behind dead. The mixes have a belief that these meetings refer to the critical behaviour of some of the flock, and that the critical behaviour of some of the flock, and that they, if found guilty, are executed on the spot. The Alpine crow, or choeard (Pyrrhocorax alpinus), has the compressed arched and sloped beak of the black bird; but its nostrils are covered with feathers like those of the crow, to which it has been annexed. It lowers of the crow, to which it has been annexed. It lowers of the crow, to which it has been annexed. It lowers of the crow, to the higher mountains, descending in immense flocks to the valleys. The nutcracker crow is platform, and descending in immense flocks to the valleys. The nutcracker crow is platform, and the clerical tonsure of the Roman Catholics. (See long of gold, surmounted alternately with four crosses and four fleurs-de-lis. Four arch-diadems, enriched with pearls, arise from these, and close under a mound en-

family in several particulars. It is not uncommon in many parts of Europe, but rarely visits England. Pennant remarks, that the specimen from which his description was taken was the only one, that he has ever heard of that was shot in the three kingdoms.

CROWBERRY. (See EMPETRACEE.)

CROWN, krown (Lat. corona), an ornament placed upon the head, denoting regal or imperial dignity. Crowns were originally garlands formed of leaves, and in that form have been used by almost every nation. The regal crown first originated in the diadem, which was a fillet fastened round the need and tree behind. was a filler rastened round the field and tied beinda. It is represented in the statues of Jupiter, the Ptolemies, and the kings of Syria. Kings were, however, generally distinguished by a fillet of a different colour from that usually worn. It was mostly in the form of a golden band, which, in time, began to form the basis of raised ornamental work, studded with coatly jewels. The crown was used by the ancient Greeks as an emblem of office, as an ornament for victors at public games, and as a mark of distinction for citizens who had games, and as a mark of distinction for citizens who had specially serred their country. Amongst the Romans the crown was still more generally used. The corona obsidionalis was the crown most highly prized. It was bestowed by an army or beleaguered garrison on the general who rescued them. It was made of leaves or wild downs set the still down and the still downs are the still downs wild flowers gathered on the spot. The civic crown, composed of oak-leaves and acorns, was the crown next

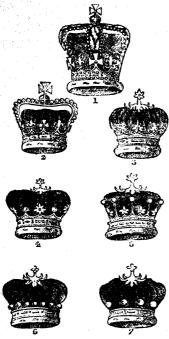

1. Civic. 3. MURALIS.

VALLARIS.

in esteem. It was bestowed upon any soldier who saved the life of a Roman citizen in battle. The man who gained it was entitled to many privileges. The mural crown, made of gold and surmounted with turrets or battlements, was bestowed upon the soldier who first scaled the ramparts of a besieged city. corona vallaris was bestowed on the person who first mounted the rampart or entered the camp of an mounted the rampart or entered the camp of an enemy; and the corona navalis was bestowed on him who first boarded an enemy's ship. Both the mural and civic crowns are used at the present time in heraldry. The triumphal crown was of three kinds, and was bestowed upon generals who had obtained a triumph. Several other crowns of different forms were worn by the Romans. Among these may be mentioned the sacerdotal crown, sometimes made of gold, some-times of cars of corn, and sometimes of olive leaves. It was worn by the priest and bystanders during a sacrifice. The funeral or sepulchral crown was placed upon the head of the dead. In Greece these crowns were usually made of parsley, The convival crown was a wreath of flowers worn on festive occasions. The nuptial crown was a wreath of verbens placked by the bride and worn by her. The natal crown was a chaplet hung over the door of a chamber where a child was born. — (Ref. Smith's Dictionary.) The crown is a term often used in Great Britain in order to designate

#### Crown Lands

signed with a cross pattée. The gold circle is also adorned with diamonds, sapphires, rabies, pearls, &c. The crowns worn by princes and noblemen are called exponents, that of the prince of Wales (2) is composed of a circle or fillet of gold; four crosses pattées are placed or mother than the between the area community. round the edge between the same number of fleurs-de-lis. From the two centre crosses a bent arch extends, surmounted by a mound and cross. The coronet of a duke (3) is a circle of gold, richly chased, having on the

CROWN AND CORONETS.

edge eight strawberry-leaves; that of a marquis, (4) a circle set round with four strawberry-leaves, and as many pearls interposed on pyramidal points. In an earl's coronet (5) there are eight pearls, set on pyramidal points, and eight strawberry-leaves, which are lower than the pearls; that of a viscount (6) is surrounded with pearls coly, the analyse heart unlimited. rounded with pearls; that of a viscount (6) is sur-rounded with pearls only, the number being unlimited; a baron's coronet (7) has only six pearls, all at equal distances. All the coronets of the British nobility, as at present worn, surround caps of crimson velvet, turned up with ermine. Viscounts and barons had rurned up with ermine. Viscounts and narons had no coronets allowed them until after Queen Bitzabeth's reign. The coronet of the kings-at-arms is a plain fillet of gold with sixteen leaves, half of which alternately are higher than the others. Miserere mei Deus is the motto on the band.

CROWN LANDS, the lands, estates, or other real property belonging to the crown or sovereign. The crown lands of Eugland are now contracted within narrow bounds, having been granted away at various times to subjects. William III. so impoverished the crown property in this way, that an act was passed by which it was decreed that all grants of crown lauds for more

# Cruciferm

on the lower corners of the frame-work, and are fitted into a central vertical king-post near the top of the pertition. In this case the crown-post ties the heist sound joiste of the partition, and affords a means of

cupport to the centre of the floor above.

CROWN-WORK, krown'-wurk, in Mil., the name g
to outworks of a peculiar form, somewhat resem the general outline of a crown, situated beyond the principal works of any fortified place. They was formerly called horn-works, consisting of two con-verging flanks, connected at the ends nearest the country by a rampart with a re-entering angle in the centre, the whole work being like the letter M in form The most common form now adopted by military engineers for a crown-work is that of a front consisting of two of the faces of a regular polygonal fortification, such as surrounds a citadel, or, in other words, a projecting bastion in the centre of the work, with a dend-bastion on either side, connected with it by curtains inclined to each other at a certain angle. This front is connected with the main works by long flanks from the salient angles of the demi-bastions, converging as they approach the works: the whole is surrounded by a ditch which joins the main ditch. Sometimes is ravelin is constructed to defend the curtain of the weakest face of a fortification, and strengthened by a surrounding crown-work. The best example of this kind of work is the double crown-work at Metz, executed by Cormontaingue.

cuted by Cormontaingue.

CROZOFHORA, kro-zo-fo'-ra, in Bot., a gen. of plants
belonging to the nat. ord. Euphorbiacea, and containing one remarkable species, namely, C. tinctoria, a
native of the south of France. This yields, by expression, a green juice, which is converted, by the combined action of ammonia and the air, into the purplish

dve called turnsole.

CRUCIBLE, kru'-se-bl (Ital. crociuolo).—In Chem., crucibles are vessels made of some material capable of resisting a high temperature, used by chemists and metallurgists for fusing metals or chemical compounds. According to the material to be melted and the heat required for fusion, they are made and the heat required for fusion, they are made of platinum, iron, plumbago, porcelain, clay, or lime. Those made of hard refractory clay, such as the Cornish or Hessian crueibles, are most without melting. Plumbago crucibles serve a double purpose, acting not only as vessels, but as reducing agents. Platinum crucibles are used in operations where the results are such as server as the corn where the control of the control agents. Platinum crucibles are used in opera-tions where a clay crucible would be acted on by the fluxes employed. Where a very high temperature is required, as, for instance, in melting platinum, a lime crucible is used. Lately, Messrs, Johnson and Matthey have introduced crucibles made of an alloy of platinum and iridium, which have many advantages over those made of platinum only. (For an account of the manufacture of plumbago crucibles, see Plum-BAGO.)

CRUCIPERE, or BRASSICACEE, kru-sif'-e-re (Lat. crux, cross; fero, I bear), in Bot., the Cruciferous or Cabbage fam., a nat. ord. of dicotyledonous plants in the sub-class Thulamiflora, having the following well-marked characters:—The leaves are alternate, and without stipules. The flowers are usually arranged in racences, are generally without bracts, and mostly yellow or white, seldom purple, sometimes a mixture of these colours. The sepals are four in number. of these colours. The sepals are four in number-deciduous, imbricate, or valvate. The petals are also four, hypogynous, crimiate, alternate with the sepals, iour,—hypogynous, crusiate, alternate with the sepany, and deciduous. The stamens are tetradynamous (six in number, four of which are long and two short). The thalamus is furnished with green glands placed between the stamens and the ovary. The ovary is superior, one-celled, or usually two-celled, in consequence of two parietal placentas meeting in the middle and forming a spurious disseptment or partition. Stigmas two, situated opposite the placentus. The fruit, which is termed a siliqua or silicula, is one-celled, or spuriously two-celled, and one- or many seeded. The seeds are stalked, and have no abunnent of the stalked and have no abunnent of the seeds are stalked, and have no abunnent of the seeds are stalked, and have no abunnent of the seeds are stalked, and have no abunnent of the seeds are stalked, and have no abunnent of the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the seeds are stalked, and have no abunnent or seed as the se it was decreed that all grants of crown lands for more than thirty-one years are void.

Onown-post, iron-poast, in Build., the name given to the vertical trues or post that rises from the horizontal tie-beam of two rafters to the point in which the rafters meet. It is also called a king-post. This formation is also found in what is called a king-post artition, in which the vertical timbers between the joists at the top and bottom of the partition are joists at the top and bottom of the partition are stated, and have no albument ing of a spurious disseptment or partition. Stigmas two, situated opposite the placents. The fruit, which is termed a siliqua or silicula, is one-tied, and one- or many seeded. The seeds are stalked, and have no albument in order is one of the most natural known, and is minerally European. There are 195 genera, consistence in which the rafters which bear of a bottom of the partition are initially further are principally best baccous plants. If ordinary care be observed, they are not likely to be confounded with plants of any

other order except Copportance. The cruciferous flowers may, however, be always distinguished from those of the latter order by their stamens, which, though always tetradynamous, are never raised above the corolls upon a lengthened thalamus or stalk. The general properties of the Crucifero are almost as definite as the botanical characters. The possession of anticorbutic and stimulant properties, combined with an aorid flavour, may be said to constitute a universal character. The puncency of cruciferous plants depends on a volatile oil composed of carbon, hydrogen, nitrogen, exygen, and sulphur. An oil expressed from the seeds is one of the most important products. None of the plants of the order, with one or two doubtful exceptions, are poisonous; many of them are esculent exgetables. The disagreeable odour emitted by them which they contain. (See Brassica, Crambr, Mastratum, Sinapis.)

ORECIFICION, kru-se-fix'-zhun (Lat. crux, a cross, and facio, in make), was one of the most ancient modes of inflicting the punishment of death. At first, probably, it was inflicted by merely fastening the victim to a tree and leaving him thus to perish of want, or to be devoured by wild beasts. Afterwards crosses, or cross pieces of wood, in various forms, came to be used. The usual forms of cross were that resembling the letter X, commonly called the St. Andrew's cross; that in the form of the letter T, consisting of an upright piece of timber with a transverse piece on the top; and the let-in cross, in which the transverse piece of timber was let into the upright, but at some distance from the top, somewhat in this form †. The cross was used as an instrument of punishment by almost all the nations of antiquity,—the Greeks, Romans, Carthaginians, Jews, Syrians, Persians, &c. Its use was abolished throughout the Roman world by Constantine, and since that time it has gone out of use. Among the Carthaginians, crucifixion was inflicted on all traks of individuals, but among the Romans it was confined to slaves and the vilest malefactors. Among the latter the culprit was scourged prior to crucifixion, and was also forced to carry his cross to the place of execution. The sufferer was usually attached to the cross by means of nails driven through his hands and feet, but sometimes he was fastened with ropes. In order to hasten death, the legs were frequently broken, or the body pierced with a spear or other sharp instrument, otherwise the sufferer often lived for days

CRUSADES, kru-saids' (Lat. crux, a cross), in the history of Europe, is the mane given to certain religious wars carried on for the space of two centuries, between the Christian nations of the West and the Mohammedans, for the possession of Palestine. They received their name from the Christians engaged in them having adopted the sign of the cross. As long as the caliphs of Bagdad and their successors, the Fatimites of Egypt, were in possession of the Holy Land, the Christians had full liberty to visit the succedplaces; but after the conquest of Palestine by the Turks, the pilgrims were subjected to cruel treatment, and Europe was filled with their complaints. At length, Peter of Amiens, known as Peter the Hermit, who had visited the Holy Land and witnessed the cruelties perpetrated by the Turks, set out on a pilgrimage through Europe, everywhere inflaming the minds of the people With accounts of what he had seen, and producing the most extraordinary excitement. The pope, Torban II., was not slow in taking advantage of this state of things, and, in 1095, summoned two councils, at which the war was agreed upon, and the like of August, 1096, was fixed for the departure of the army. The first army consisted of about 40,000 men, chiefly Franchmen, Normans, Dutch, Germans, and Italians, but totally undisciplined. They marched through Hungary and Servia, where many of them perished, and the rest were totally defeuted and almost annibilated by the Turks, et Nicres, in Bithynia. It was succeeded, however, by a well-disciplined army of about 600,000 strong, comprising many of the mommand of Godfrey of Bouillon, duke of Lorraine.

They marched into Asia and took Nices, and afterwards Antioch and Bdesse. At length, on the little of July, 1999, after a siege of about six weeks, they obtained possession of Jerusalem, and Godfrey of Bouillon was chosen king. For nearly half a century the conquerors not only maintained their position, but greatly extended their territories, till 1144, when the city of Edesse was taken by the emir of Mosul. A second crusade was preached by St. Bernard, abbt of Clairyan; and two immense armies, estimated to-Scientific transact was pleased by the contract was the contract of a million of men, were raised, under the command of Courad III., emperor of Garmany, and Louis VII., king of France. Through the many, and Louis VII., king of France. Through the treachery, however, of the Greek emperor, Manuel Comnenus, this vast army was all but destroyed by the Turks, and, after an unsuccessful attempt to reduce Damascus, the residue had to make their way back to Burope. The news of the capture of Jerusalem by Saladin (1187), and the fall of the Christian kingdom of Palestine, brought about the Third Crusade. The leaders of this new expedition were Frederick Barbarossa, emperor of Germany, Philip Augustus, king of France, and Richard Cœur-de-Lion, king of England. Barbarossa first took the field in 1189, and defeated the sultan at Iconium; but, in approaching Syria, he was seized with a fever, and died in 1199. Richard and Philip arrived in Syria some months later with a great army, and were joined by the army of Barbarossa. After a lengthened siege they obtained possession of the city of Acre; but Philip soon afterwards returned to France, and Richard concluded a peace with Saladin, in terms of which the Christians of the West were to be allowed to make pilgrimages to Jeruthe Turks, and, after an unsuccessful attempt to reduce with Saindin, in terms of which the Christians of the West were to be allowed to make pilgrimages to Jerusalem without molestation. The Fourth Crusade was intended, like the others, for the conquest of the Holy Land; but, instead of that, it directed its efforts against the Greek empire. Assembling at Venice in 1203, the doge of that city induced them to take the terms of Tares in Disputsion and Source to take the town of Zara, in Dalmatia, and afterwards they took up the cause of Alexius, whose father, Isaac Augelos, had been driven from the Greek throne by his own brother. They took Constantinople, and, after elevating to the throne several princes successively, they at length elevated to it their own chief, Baldwin, count of Flanders, giving him a fourth part of the empire, and dividing the rest among themselves. He and his successors held the empire of the East for upwards of half a century. The Fifth Crusade commenced by the march of a body of troops, under the command of Andrew II. of Hungary, against the Turks, in 1217. After a series of successes in Palestine and Egypt, they suffered a severe reverse before Cairo, and were obliged to sue for leave to return home in 1221. Five years later. K ederick II. of Germany put himself at the head of a considerable army, and set out for the conquest of the Holy Land. The expedition was successful, and Frederick, after receiving from the sultan possession of Jerusalem, and being crowned king, returned home in 1229. Jerusalem and Palestine having again fallen into the hands of the Turks in 1224. the Sixth Crusade was undertaken by Louis IX. of France in 1249. He marched into Egypt, took Damietta; but was afterwards defeated, the greater part of his army cut off, and himself taken prisoner. He obtained his liberty and that of his followers on agreeing to pay a heavy ransom, and then returned home.
Louis, however, did not give up the idea of reconquering the Holy Land, and a few years later he originated
the Seventh and last Crusade against the Holy Land. He died at Tunis, on his way to Palestine, and the command of the expedition devolved upon Edward, prince of England, afterwards Edward I. He marched into Palestine, took the town of Nazareth, but effected nothing further of consequence, and soon after returned Acre and a few other towns still remeined to home. nome. Acre and a lew other towns said aminos to the Christians, and were defended for some time by the Templars and other military knights; but at length Acre capitulated in 1291, and the other towns soon after followed its example. How far the crusades have been of advantage or otherwise to the subsequent progress of Europe, is a question which has given rise to much discussion. They were undoubtedly carried on at an enormous expense of human life, and, in the end, produced no material result, while, during their continuance, they necessarily retarded all progress in

## Crusos, Accademia della

Crystallography

the peaceful pursuits of the arts or manufactures; but on the other hand, we believe that they have a recised a most beneficial influence upon the civilization of Burope. The various nations of Europe were united together in one common cause, and taught to know and sympathize with each other; they were brought into contact with two new civilizations,—the Greek and the Saracenic, each more advanced and refined than their own; and commercial enterprise received from the crusades its first and its greatest stimulus.

CRUSCA, ACCADRMIA DELLA, kroos ka äk-ka-dai'. ms-a del'-la (Ital., the academy of the bran or chaff) was the name of one of the earliest, and one of the most celebrated of the societies of modern Europe. founded at Florence in 1582, chiefly through the exertions of the poet Antonio Francesco Grazzini, and was so called from its chief object being to sift or purify the national language. The great work of the academy was the "Vocabolario degli Accademici della Crusca" (or Dictionary of the Italian Language), which was first published at Venice in 1612, and has since gone through numerous editions, being still regarded as the standard authority on the Italian language. This society has recently been incorporated with two other societies, under the name of the Royal Florentine Academy.

CRUST OF THE EARTH. (See GEOLOGY.)
CRUST OF THE EARTH. (See GEOLOGY.)
CRUST OEA, krus-fai'-she-a (Lat. crusta, a hard shell),
a class of articulated animals whose external covering is less solid than that of the majority of testaccous mollusca, but much firmer and harder than the skin of the naked mollusca. This tegumentary skeleton may be regarded as a kind of epidermis, for beneath it is found a membrane like the true skin of higher animals At certain times this solid envelope detaches itself and falls off, as the epidermis of reptiles separates itself from their bodies. With the crawfish this shell-shedding, or ecdysis, as it is called, is preceded by a few days sickness and fasting, and at that time the carapage, or upper shell, becomes loosened from the corium to which it is attached. The corium begins forthwith to secrete a new shell, which, at first soft and mem-branous, becomes gradually harder and harder, and is at last calcareous. When all connection is broken off, the animal sets about freeing itself of the incumbrance It rubs its legs one against the other, and finally throws itself upon its back, and in that situation begins to swell out and shake itself, till it tears the membrane that attaches the carapace to the abdomen. greatest difficulty occurs in freeing the extremities, nor could they be extricated at all, did not the old shell split longitudinally. The entire process is completed in half an hour; but it takes from twenty hours to three days for the conversion of the soft and membranous integuments into a firm case similar to that lately abandoned. While this transformation is taking place, the muscles of the animal are flaccid, and the flesh altogether unfit to be caten. An exception to this rule, however, would seem to occur in the case of the land crab; for, according to all that has been written on the subject, the latter animal is never so delicious

Sa during the moulting period.

CHYPT, kript (Gr. kruptein, to conceal), a low chamber under a charch or cathedral, with a vaulted roof, the groined arches of which spring from short but massive columns. Sometimes the crypt extends under the entire church, as at Canterbury cathedral; but they are generally of much smaller dimensions. Divine service was formerly performed in them, and they were also used as places of burial.

CRYPTOGRAPHY. (See SECRET WRITING.)

CRYSTALLINE LENS, kris'-tal-line (Lat. orystallus, &

CRYSTALIANE LENS, krist-tail-time (Lat. crystalius, a crystal; lens), in Anat., is the lens of the eye, a lentiform pellucid substance, inclosed in a membranous capsule, and situated in a depression in the anterior part of the vitreous humour. (See EYE.)

CRYSTALIZATION, kris-till-ti-zai's-ham, in Chem., crystallization may be defined as the spontaneous assumption of well-defined geometrical forms by hodies in passing from the fluid or seriform state to the rollid coefficient. Rodges not causalle of assuming the solid condition. Bodies not capable of assuming the crystalline form are termed amorphous or colloid; those which form crystals, orystolloid. When a substance crystallizes in two distinct forms, which cannot be derived from the same original, it is said to be dimorphous to the control of th

phous. Sulphur, for instance, will crystallize in ce-tahedra or prismatic crystals. Some substances are even trimorphous. Sulphate of nickel crystallizes in ishedra or prismatic crystals. Some substances are even trimorphous. Sulphate of nickel crystallizes in right rhombic prisms, square-based octabedra, and obique rhombic prisms, according to the temperature at the time of evaporation. Bodias crystallizing in similar forms are called isome-pase. The alumn and fluor spar; carbon, gold, copper, and their compounds; the potassium compounds of chlorine, iodine, bromine, and fluorine, form isomorphous groups. Crystallization may be effected in several ways,—by evaporation, by sublimation, by fusion, or by slow electrical action. It sometimes happens that precipitates are thrown down in a crystalline form; thus, when tartaric acid is added to a solution of potash, the tartrate of potash added to a solution of potash, the tartrate of potash falls down in minute crystals. Crystallization by evaporation is effected either by allowing a hot saturated solution of the salt to cool gradually or by spontaneous evaporation. In the former case the masses of crystals are small and confused. Where single perfect crystals are required, the method of crystal-feeding invented by Leblane must be resorted to. A small but perfect crystal is first obtained by one of the methods meationed, and placed in a cold concentrated but not saturated obtained by the subtraction of the subtraction. rated solution of the substance in question, after which the crystal is turned regularly twice every day, taking care to expose a fresh surface each time until the crystal has reached the desired size. As the solution becomes weaker, it should be replaced by a fresh quantity of the original strength. Great care must be taken not to use a saturated solution, otherwise fresh crystals will form in the vessel and on the original crystal. A glass plate may be used to lay the crystal on in the solution, and a pair of horn or box-wood tweezers are better than the fingers for turning it. By these means crystals of enormous size may be made. The solution should, as much as possible, be kept at the same temperature, and the crystal should be turned very regularly. Crystallization by fusion is resorted to in the case of metals and other insoluble substances. The metal or other pody is melted in a ladle or cruthe metal or other body is incited in a ladie of era-cible, and allowed to cool until the top crust is solid; it is then pierced with an iron rod, and the melted substance not yet solidified is allowed to run out. Fine masses of crystals of bismuth and sulphur may be obtained in this way. Many salts do not appear to be capable of crystallizing without holding a certain portion of water in combination, termed water of crystallization. Thus ordinary carbonate of soda has ten equivalents of water united with it. Some crystals part with this water very easily, losing their crystalline form and falling to powder merely by exposure to the atmosphere. Such salts are called *efforescent*, in contradistinction to those which absorb water from the atmosphere, which are termed deliquescent. Many salts have the property of crystallizing without water of crystallization; others, again, crystallize in different forms, according to the number of equivalents of water they contain. Biborate of soda, or borax, for instance, crystallizes in prisms or octahedra, according as it contains ten or five atoms of water of crystallization. The forms which crystals assume are also influenced by the purity of the solution from which they are crystallized; for instance, iodide of potassium assumes a prismatic form when crystallized from a neutral solution, but if from one containing carbonate of potash, the resulting crystals are cubical. As to the orce causing crystallization we as yet know but little; all we know at present is, that electricity and light both accelerate crystallization. If a weak voltage current be passed through a solution of silies, it will gra-dually crystallize round the wires; and if campbor be exposed to the light, crystals will form thicker on the most illuminated side.

CRYSTALLOGRAPHY, kris-tal-log'-grit-fe (Lat. crystal-CRYSTALLOGAPHY, krus-fall-log-gride (Lat. crystalus, a crystal; Gr. graphs, writing). — Although the forms of crystals appear to be infinite, yet, upon carefully considering their axes, angles, faces, and edges; they are found to fall into six well-defined groups, which are distinguished from each other by the relative positions and lengths of their axes. These six groups are again subdivided into divisions according to the averagement of their are with carnet to their averagement of their planes with respect to their averagement of their spaces. arrangement of their planes with respect to their axes.
The subject of crystallography is a very difficult one, and only to be learnt by means of an extensive series

of figures or models. It will therefore be necessary to treat the matter somewhat cursorily, referring the student to several standard works upon the subject. The six crystalline systems mentioned are:—1. Regular. The cube, octahedron, and rhombic dodecahedron are the principal members of this system. 2. Square prissatic, in which two of the axes only are equal, all three being rectangular. 3. Right prismatic, in which all the axes are expend and all rectangular. It may perhaps assist the memory if it is borne in mind that means of the above systems the whole of the axes are rectangular, while in the following three the axes are rectangular, while in the following three the axes are rectangular, while in the following three the axes are all inclined to each other. 4. Rhombohadral, in which the three axes are equal but not rectangular. 5. Oblique prismatic, one axis rectangular to two, but all means of the store are sare equal but not rectangular. 5. Oblique prismatic, one axis rectangular to two, but all means of the store are sure shade off gradually into each other. Thus, the cube, by being slightly increased on one of its faces, becomes a square prism: and the aquare prism; by having one of its sides slightly enlarged, becomes a right prism. Many forms are derived from each other by having slices removed from their angles or edges. Thus the octahedron may be modified into a cube by having its angles gradually sliced away, and into the rhombic dodecahedron by having its edges treated in the same manner. A few turnips or potatoes and a sharp knife will afford the student much information in this way. Thus alum, which crystallizes as an octahedron, is often found erystallized with its edges or angles sliced away, and approaching the form of one or other of the forms mentioned. (See also Isomorphism, and Follmore of the subject in Odline's (Remister, part I

Odling's Chemistry, part 1.

CUBE, kube (Gr. kubes, a die), in Geom., is a solid body terminated by six square equal faces, and eccupying among bodies a place analogous to that of the square among surfaces. It is also called the hexabedron, by reason of its possessing six sides. One of the most celebrated problems in the history of geometrical science is the duplication of the cube, i.e. the construction of a cube which shall have twice the volume of a given cube. In the time of Plato, it was a constant subject of controversy with geometers, who, however, tailed to solve the problem, because the straight line and circle, which were the only lines admitted into their calculations, are not sufficient for

the cubation of solids.

OUBE ROOT is a number or quantity which, if multiplied into itself, and then again by the product, produces the cube; or, when twice multiplied into itself, produces the number or quantity of which it is the root. Thus 5 is the cube root of 125, because

5×5=25×5=125.

Cubers. Cubers. Columbus. (See Cubers.)

Ousir, ku-bit (Inc. cubitus), a measure of length employed by the ancients, and more especially by the Hebrews. It was originally the distance from the elbow to the tip of the middle finger. According to some authorities, there were two cubits in use by the Jews,—the sacred and the common cubit. The former was twenty-one inches long and the latter eighteen sinches. Calmet, however, states his belief that the second, or shorter cubit, was not introduced until after the Babylonian captivity. Hence Ezckiel's precaution (Ezck, zl. 5) in speaking of the cubit as a cubit and a hand-breadth. The exact length of the cubit is not known; it has been stated to be 1 foot 9585 inches, and a hand-breadth 3684 inches, in the tables of measure affixed to several versions of the authorized Bible.

CTCRING-STOOL. (See DUCKING-STOOL.)

Oucnon, kook-oo (Lat. osculus, Fr. coscout), (Cusulus canorus).—This bird, which derives its mane from the peculiar sound of its note, is very widthy diffused. It is found in India and in Africa, and migrates northward in summer, even to Lapland and Kamtohaths. It makes its appearance amougst us in April, and disappears again by about the middle of August. It would seem that love is a passion that occupies very little of the cuckoo's consideration. There is no pairing or continued attachment between the male and female, and the latter generally, if not always, lays her eggs in the nest of some other smaller bird, leaving their hatching and future maintenance to fate. The gratitude of the foster child is of a piece with its parent's heartlessness. Mr. Selby asserts that, when

hatched, the young cuckoo has between its shoulders a depression in which it lodges any burden it wishes to carry to the edge of the nest for ejectment; that, at the expiration of twelve days, the hollow is filled up, and that, should the proper occupants of the nest chance to remain till then, the young cuckoo no more molests them. The hedge-sparrow, the pied wagtail, and the yellowbammer, are the birds commonly selected by the cuckoo for imposition. In the early part of the

CUCKOO.

summer of 1828, a cuckoo, having previously turned out the eggs from a water wagtail's nest, which was built in a small hole in a garden-wall at Arbury (the seat of Francis Newdegate, Esq.), deposited her own egg in their place. When the egg was hatched, the young intruder was fed by the water wartails till he became too bulky for his confined and narrow quarters, and in a fidgety, fit fell to the ground. In this predicament he was found by the gardener, who picked him up and put him into a wire eage, which was placed on the top of a wall not far from the place of his birth. Instead, however, of its foster parent the wagtail coming to feed it, there appeared at its prison-lars a friendly bedge-sparrow, who, day after day and at very fre-quent intervals, continued to bring it food, until it was dent intervals, continued to be set at berty. Bishop Stanley relates ar instance of an unfiedged cuckoo being placed in the same cage with a young thrush. The cuckoo was either too idle or unable to feed itself: so the good-natured thrush kindly performed the operation for him. One day a tempting worm was offered at the wires, and at once the thrush went to it. Whether its original intention was to give it to its patient can never be known; if so, however, the sleek plump thing hanging in the thrush's very beak was too great a temptation: it swallowed it. It seemed that the cuckoo had made sure that the worm was coming up to him, and when he discovered his error he hopped ficreely down, and, with one blow of its cruel besk, took one of the thrush's eyes out. Even in this maimed condition the patient nurse continued to wait on its tyrant patient, and never ceased to do so till the cuckoo was hig enough to shift for itself. The gilded cuckeo (Cuculus auratus) is an inhabitant of the Cape of Good Hope, and extremely common in Caffaria. It is a very beautiful bird, the chief of the plumage being brilliant green with golden reflections. It is about seven inches long. Like the common cuckoo, it deposits its egg in the nests of other birds, and, unless Vaillant was mistaken, in a way that puts aside the notion that the hen-cuckoo lays them where they are to be hatched by another bird. While out shooting with his man Kloac, he brought down a golden cuckoo with one of the eggs of its species, and evidently freshly lain, in its throat; and it then occurred to him that his attendant had frequently brought him a bird of this kind, with the exclamation, "This one dropped an egg as she fell from the tree." Later in the day another cuckoo was shot by Vaillant, with an egg in its gullet. "I was convinced from this circumstance," writes the sporting naturalist, "that the female cuckoo deposite

### Cuckoo-Flower

her egg in the next of snother bird by conveying it thither in her beak." Besides those noticed, there is susser in ner near. Heades those noticed, there is the spotted outloo (Oxylophus glandarius), an inhabit-sate of the north of Europe; the oriental anckoo (Eu-dynamys crientalis), found in the East Indies; and the yellow-billed American cuckoo (Coccysus americanus), likewise called the cow-bird and the rain-crow.

CUCKOO-FLOWER. (See CARDAMINE.)

CUCHOO-PINT. (See ARUM.)
CUCUMBER. (See CUCUMES.)
CUCUMBER, ku-kw'-mis, in Bot., a gen. of plants be-

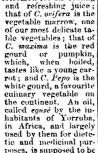

CUCHMBER.

longing to the nat. ord. Cucurbitacea. The fruit of C. sativus is the conmoncucumber, and that of C. Melo the melon. The fruits of the spe cies C. Hardwickti and Pseudo-colocynthus are said to be powerfully cathartic.

CUCUBBITA, ku-kur'bit-a (Lat. cucurbita), in Bot., the typical gen of the nat. ord. Cucurbitaceæ. The fruits of several species are em-

ployed as articles of food; thus, that of C. Citrulius is the water-melon, so highly esteemed for its cooling

the produce of one or more species of this genus.

CUCURBITACEE, ku-kur-bit-ai'-se-e, in Bot., the Gourd or Cucumber fam., a nat. ord. of dicotyledonous plants in the sub-class Calycifloræ. Upwards of 60 genera have been described, and these include more than 300 species. The plants are natives of hot cli-mates in almost every part of the world; they abound in the East Indies, many occur in Peru and Brazil, a few are found in Europe and North America, and one species only, Bryonia dioica, in the British isles. They are all herbs with tuberous or fibrous roots, which are annual or perennial, and with stems which are generally succeivent, and either prostrate or climbing by means of tendrils. The leaves are rough, alternate, and radiate-veined. The flowers are unisexual, mopercious, or directous. The calyxis monosepalous, and in the female flowers, superior. The corolla is monopetalous, four or live-parted, sometimes fringed, with atrongly-marked reticulated veins, perigynous, and occasionally scarcely distinguishable from the calyx. The male or sterile flower has generally five stamens which are epipetalous, and either distinct, or monadelphous, or triadelphous, the anthers being two-celled namally long and sinuous, rarely straight. Now and then male flowers are found with only two or three then male flowers are found with only two or three stamens. In the fertile or female flower the ovary is inferior, the style is short, and the stigmas are more or less dilated. The fruit is usually a pepo, as in the ounquinder; or rarely a succulent berry, as in the bryony. The seeds are more or less flattened and exhibitions. An acrid, bitter, purgative principle characterizes the plants of this order, and is especially exhibition in the pulp surrounding the seeds. In some sultivated species the acridity is scarcely perceptible, and the fruits are edible. (See CUCUMIS, CUCUMBITA.)

Que, ku, the last words of a speech spoken on the

## Cultivation of the Soil

stage, which the actor who is to answer catches at regards as an intimation to begin. It is also applied to any hint given to an actor on the stage, as to what he has to do or say.

CUIBASS. (See BREASTPLATE.)

CUIBASS. ESPENDENCHARE, COLUMN SERVICE back- and breastplates. We have no cavalry so called in the British army, although the Life Guards and Horse Guards wear cuirasses. The cuirass was ori-ginally formed of thick leather, which was ball proof, —whence its name; but when this material was no longer used, the name was retained, and applied to the metal plates which superseded the leathern armour.

CULDERS, kull-deez, the name given to an ancient religious order of ecclesiastics that existed in Ireland. Scotland, and the northern parts of England. The derivation of the name is uncertain, some tracing it to the Gaelic, others to the Latin. According to Bu-chanau, it is a corruption of cultores Dei, worshippers of God. The time of their first appearance, and the character of their institutions, have been no less matter of dispute than their name. Some date their origin from the middle of the 6th century, and attribute their institution to Columba, who came over from Ireland to the island of Iona, on the west coast of Scotland, where he established a monastery, and from which he sent forth his disciples to diffuse the knowledge of Christianity. Having no correspondence with the see of Rome, they are said to have been free from the corruptions that, at a later period, crept into that church, as saint and relic worship, auricular confession, penance, &c.; and their time for the celebration of Easter differed from that of the Church of Rome. They prosecuted their missionary labours throughout Ireland, Scotland, and the northern parts of England, and established flourishing settlements in various parts, after the model of lone. Many of these were in the form of colleges, where instruction was given to youth. In Scotland their chief sellements were, besides Iona, on the island of St. Serf in Lochleves, at St. Andrews, Dunkeld, Abernethy in Perthasire, Monifeith near Dundee, and Monymusk in Abendeenshire. The Culdees gradually lost their power before the growing influence of the Church of Rome. the crecitor of bishopries under the patronage of the kings of Scotland being a death-blow to their independent existence; and their suppression is generally dated from the end of the 13th century, when the Culdees of St. Andrews made their last attempt at resisting the usurpations of the bishop of that see, though it is generally believed that numbers continued to hold their principles down nearly to the time of the There are others who hold that there is Reformation. There are others who hold that there is no trustworthy evidence of the existence of the Culdeen prior to the middle of the 9th century; that there is no reason to suppose that they differed in any material point of faith, discipline, or ritual from the Church of Rome; and that, in reality, they were a mere collec-tion of monastic institutions in connection with the Catholic hierarchy.

Culex, ku'-leks (Lat., a gnat), in Ent., a gen. of the Diptera or two-winged insects, constituting the Guat fam. They are characterized by their length of probose is and their finely-tutted antenne. (See Guat.) Mosovito.)

CULM, kulm, in Min., a slaty kind of anthracite, occurring in Wales and North Devon. The strate in which it is found are often called the culm measures.

CULMINATION, kul-min-ai'-shun (Lat. culmen, the top of anything).—When any heavenly body is on the meridian, it has then attained the highest point of the daily course, and is therefore said to culminate. The sun culminates at mid-day, the moon at midnight, when it is full moon.

CULTIVATION OF THE SOIL, kul-tiv-ai'-shun, the art of preparing the soil for those particular crops which it is required to bear. The ordinary agricultural implements used for this purpose are the plough, the spade, and the loce. In some modified form these spade, and the loce. space, and the noe. In some modified toric traces instruments have been in use among all nations, at all times. The soil, by their means, is stirred and exposed to the action of the atmosphere, and loosened, so that the roots of plants may make their way more estily

### Culverin

through it. Other objects are also effected by com-plete inversion and careful cultivation of the soil. The piete inversion and carretti duinvatton of the soil. The surface-plants are buried and allowed to decay; water in excess passes through it in wet weather; and in dry seasons more moisture is retained. In dry climates the soil requires to be well ploughed and rolled, but in wet climates these operations must be restricted.

CULVERIN, kul'-ver-in (Fr. coulevrine), the name of a piece of ordnance, used in the 16th and 17th centuries, of great length, and formed to throw a ball to a con-siderable distance. It was 5; inches in the bore, and threw a ball about 18 lbs. in weight. The bore of the demi-converin was 4 inches, and the weight of the ball about 9 lbs. Queen Elizabeth's pocket pistol at Dover Castle is a culverin.

CULVERT, kul'-vert, a barrel-drain of small diameter, or an arched water-course for the conveyance of water

or an arched water-course for the conveyance of water under roads, railways, embaukments, and canals.

CUMINUM, ku-mi-num (Gr. kuminon), in Bot., a gen. of composite plants. C. Cyminum, the cumin, is a dwarf fennel-looking plant, cultivated in the south of Europe and Asia Minor for its fruits, which are hot and aromatic, like those of the caraway and anise.

CUNRIFORM, ku-ne'-e-form (Lat. cuneus, a wedge, and CONEIFORN, EU-ne-cjorm (Lat. caneas, a weige, some form), is the name given to an ancient species of written language found on the monuments of the ancient Assyrian, Babylonian, and Persian empires. It is so called from the letters being composed of parts resembling a wedge, a nail, or an arrow-head. It is found carved in rocks and sculptures, or stamped on bricks and tiles; and is met with on the uncient monuments of Persepolis, and other cities of the Persian empire, among the ruins of Babylon and Nineveh, and even in Egypt. It appears to have been first employed in Assyria and Media, and to have subsequently spread over the whole extent of the Persian empire. are three distinct alphabets or kinds of cuncitorm are three distinct alphabets or kinds of cunciform writing, and which are mostly found together in parallel columns, being translations of each other. The most ancient of these is the Assyrian, which consists of about 400 different characters, and is the one which has given most trouble to philologists, and in which least progress has been made. The second of these is called the Median, which is a modification of the first, and consists of about 100 characters. The most second is the Pareira, which consists of only 30 to 44. recent is the Persian, which consists of only 39 to 44 letters. It is much more refined than the others, and the forms are much less complicated. The letters here are all very distinctly formed, none being at all doubtful, and the words are separated from each other by an oblique stroke. This language is believed to be the original of the modern Persian, and to be nearly allied to the Sanscrit. There is every reason to believe that the employment of the cunciform character originated in Assyria, while the system of writing to which it was adapted was borrowed from Egypt. "The whole adapted was borrowed from Egypt. "The whole structure of the Assyrian graphic system," says Rawlinson, "evidently betrays an Egyptian origin. The alphabet is partly ideographic and partly phonetic, and the phonetic signs are in some cases syllabic, and in others literal. Where a sign represents a syllable, I conjecture that the syllable in question may have been the specific name of the object which the sign was supposed to depict; whilst in cases where a single alphabetical power appertains to the sign, it would seem as if that power had been the dominant sound in the name of the object." Much progress has already been Much progress has already been made in deciphering these ancient records, from which we may expect much light to be thrown on the early history of the world. The first accounts of the cuneiform characters were brought to Europe about the beginning of the 17th century, and some time afterwards imperfect copies of them were published. The first publication of a connected inscription was made by Le-Bruyn at Amsterdam, in 1714; and, subsequently, Niebuhr-published copies of some which he had found at Persepolis and elsewhere, and which were more accurate than any that had appeared before. Still, for accurate than any that has appeared cerore. Stil, for long after this, nothing was done towards the decipher-ing of the language. Many, indeed, were of opinion that they belonged to no language,—that they were mere ornaments carved at the caprice of the archi-tect, or charms, or talismanic signs; while at least one author saw in them only the destructive work of worms. Grotefend, of Hanover, was the first that made any

## Cupressus

progress in the deciphering of these characters, brought the result of his labours before the Acad of Göttingen in 1802. The labours of Grotefend was not followed up by others for the next twenty years but since that time there have been many able an

but since that time there have been many able and active labourers in the field; among whom we may mention Rask, Burnouf, Lassen, Westergaard, Rawlinson, Renau, Norris, Hincks, Oppert.
CUNONIACE, ka-non-e-di-se-e, in Bot., a nat. ord. of dicotyledonous plants in the sub-class Calyeifform. They are nearly allied to the Saxifyagaces, but differ from them in Being trees or ahrubs, with opposite leaves and large interpetiolar stipules. They are natives of South America, the Cape, the East Indies, and Australia. Most of them have astrippent proper-

natives of South America, the Cape, the East Indies, and Australia. Most of them have astringent properties, and some have been used for tanning.

CUPANIA, ku-pai'-ni-a (in honour of Cupani, an Italian monk and botanist), in Bot., a gen. of plants belonging to the nat. ord. Sapindaoca. The species C. sapida flourishes in the West Indies, and is in some respects a valuable and interesting tree. The distilled

respects a valuable and interesting tree. The distilled water of the flowers is used by the negro women as a cosmetic, and the succulent, slightly acid arillus of the seed is cuten for dessert. The fruit containing the seeds is commonly known as the akee-fruit.

CUPEL, ku'-pel (Lat. cupella), in Chem., a small cup made of bone ashes, used for extracting base metals from gold and silver. The compound, on being heated in the cupel, loses the base metals by their becoming exidized, and sinking into the cupel. (See ASSAVING.)

CUPPLICATION, in Chem. (See ASSAVING.)

CUPILITEER, ku-pil-i-fer'-e, in Bot., a name given by some botanists to the Oak or Mastwort order. (See CORYLAGE.)

CUPOLA. (See DOME.)

CUPPING, kup'-ping (from the cup-like form of the glasses employed), in Surg., is the application of cupping-glasses, from which the air has been previously extracted, to the skin, with the view of attracting blood to the part, and, if necessary, abstracting it. Capping was practised by the ancients, and is frequently had recourse to in the present day. In performing the operation, the part is first washed with warm water, in order to promote the flow of blood to it, and then a small bell-shaped glass, from which the air has been partially expelled by holding it for an instant over the flame of a spirit-lamp, is immediately applied to the spot, and the usual amount of pressure on the part being thus diminished, the blood flows towards it, pro-ducing a distension of the blood-vessels and an elevaducing a distension of the blood-vessels and an eleva-tion of the surface. This is called dry cupping, and is frequently of great service in the removal of certain kinds of pain. Several glasses may be used, and usu-ally the operation is repeated five or six times. The glass is readily removed by inserting the nail of a finger between the edge of it and the skin, so as to admit the air. When it is intended to abstract blood, the cupping-glass is removed as soon as the part is sufficiently swellen, and the scarificator applied to it. This instrument contains a number of lancets (usually about ten or twelve), which, by touching a spring, are made to inflict a corresponding number of wounds, the depth of which may be regulated by the operator, Immediately on the wounds being made, the cuppingglass is applied, exhausted as before, and the blood allowed to flow into it until a sufficient quantity has been abstracted. If the blood coagulates, or the glass be full, it should be carefully removed, and the part sponged with warm water, and the glass again applied to it. Cupping is preferable to any other method of blood-letting in many kinds of inflammatory disease.

blood-letting in many kinds of inflammatory disease. Cupressus, ku-pres-sus (Gr. kuo, I produce; parisos, equal; because it bears equal branches), in Bot., the Cypress, a gen. of plants belonging to the nat. ord. Conferce. C. semperoirens is a common timbor-tree in some parts of the Levant. Its dark foliage is particularly impressive when seen near architectural works; and on this account the tree was always planted by the Moors round their splendid; palaces, and by the Romans near their villas. In the burial-grounds of Turkey and Arabis, the tombs of the faithful are generally shaded by the cypress. The timber of this and other species is very durable, and is said to resist the worm. The doors of St. Peter's church at Rome are of cypress-wood, and have hared church at Rome are of cypress-wood, and have lasted

## Cupric Acid

upwards of 1,100 years. It is supposed that the gopher-wood of the Bible was chiefly obtained from species of

this genus.

Offric Acid, ku'-prik, in Chem.—This acid never
When finely-divided occurs in a separate state. When finely divided opper is fused with nitre and hydrate of potash, a country formed, which is an exceedingly unstable sait, easily decomposed with potash, oxygen, and copper.

Cuparn, ku'-prite, in Min., the red oxide of copper, which is also known as octahedral copper-ore, from

the form of its crystals.

CURAÇOA, ku-rā-so', a sweet and agreeable liqueur obtained by digesting orange-peel in sweetened spirits and flavouring with cinnamon and cloves or mace. It is made in great perfection by the Dutch in the islands of Curação, from which it derives its name. The spirits employed in its manufacture are usually reduced to nearly 56 under proof, and each gallon contains about \$\frac{3}{2}\$ lbs. of sugar. Curaços varies in colour, the darker kinds being produced by digesting in it powdered Brazil-wood, and mellowing the colour by caramel or

burnt sugar.

CUBATE, ku'-rait (Lat. cura, care), literally signifies a person, who has the cure of souls, and in this sense it is used in the English Book of Common Prayer. Commonly, however, it is used to denote the lowest degree in the Church of England,—the person who is employed under the spiritual rector or vicar, either as assistant to him in the same church, or else in a chapel-of-ease within the same parish belonging to the mother church. A curate has to be licensed and admitted by the bishop of the diocese, or by an ordinary having episcopal jurisdiction, who also usually appoints the salary; in which case, if he be not paid, the curate has a proper remedy in the ecclesiastical court; but if he he not licensed by the bishop, he only has his remedy at common law. A curate not licensed may be removed at pleasure; but if licensed, he can only be removed by consent of the hishop, or where the rector or vicar does duty himself. A curate having no fixed estate in his curacy, not being instituted and inducted, may be removed at pleasure by the hishop or incumbent, and in such case he is usually termed "stipendiary. Where, however, the profits of a benefice are impropriate, so that both the rector and the vicar are or may be lay, the curate is "perpetual." and not removable, being the clerk employed to officiate by such impro-priators. A curate, before being licensed, must subscribe to the Thirty-nine Articles and the three articles of the 36th canon; must declare his conformity to the united Church of England and Ireland; and must take the oaths of allegiance, supremacy, and canonical obdience. In general, the stipends paid to curates are still miserably small, though they have been much improved by a recent enactment. By 1 & 2 Vict. c. 106, certain rules are leid down for fixing the amount of stipends to be reid to curate a bracker without the print of the certain rules are leid down for fixing the amount of stipend to be reid to curate a bracker without the print of the certain rules are leid down for fixing the amount of the print of stipend to be paid to curates by non-resident incumbents. The lowest stipend is fixed at £30, or the whole value of the living if less than that sum. Where the population amounts to 300, the stipend is to be £100; where 500, £120; where 750, £135; and where 1,000, £150; or the whole value of the living, if less than these sums.

CURATOR, ku-rai'-tor (Lat. curare, to take care), an officer among the ancient Romans, whose duties were very varied. In civil law, a curator was one appointed to administer the estate of any person not legally competent to manage his own property. Every person under age who was not under paternal or domestic rule, was put under the superintendence of a guardian. Up to the age of fourteen in a male minor, and twelve in a female, this guardianship was styled tutelage; from that time to the age of twenty-five it was called curatorship. The tutor, or the first guardian, was the ego of the minor; but the curator was local alter merely the representative of his ward and the ordinary administrator of his rights. Persons who recklessly squandered away their money were placed under the superintendence of a curator. Deaf and dumb persons were also considered to be legally unable to administer their affairs, and were put under similar guardianship. The curator bonorum was a trustee for the administra-tion of the affairs of absent or deceased persons, and also of insolvent debtors. After the time of Augustus 601

# Curley

several public officers were appointed who held th title of curator. There were curators of the roads who had the superintendence of the planning and repairing of the roats; the curators of public works, who had the superintendence of the public buildings, theatres, aqueducts, &c.; the curators of the river, who were the conservators of the Tiber. There were also other curators, who had the superintendence of the public games, others who administered the landst the public games; others who administered the landed properly of municipies; and others who distributed corn among the people. In the universities and in learned societies, the officers who have charge of libraries, museums, collections of natural history, &c., are called curators.

CURB-STONE, kerb, the line of stonewerk which borders the footpath of a road. It is generally made of a hard durable stone, such as granite.

CURCUMA, kur-ku'-mā (Arab. curkum), in Bot., a gen. of plants belonging to the nat. ord. Zingibaracca. The dried tubers or rhizomes of C. longa constitute. the turmeric of the shops. Turmeric is extensively cultivated in almost every part of India, being employed as a condiment by the natives. It forms the principal ingredients of curry-powder, giving to that compound its peculiar odour and bright yellow colour. compound its peculiar odour and pright years country it is used for dyeing yellow, and for making turmeric-paper, which is used as a test for free alkalies, being turned by these from a yellow to a reddish-brown colour. As a medicinal agent, turmeric is a mild aromatic. The rhizomes of another species, C. angustifolia, contain much starch, which, when extracted, forms East Indian arrowroot, or curcuma starch.

CURFEW, kur'-few (Fr. couvre feu, cover fire), the ringing of a bell as a signal to the inhabitants to exinguish their fires. This practice originated in England through William the Conqueror, who ordained, under severe penalties, that, upon the ringing of a bell at eight o'clock in the evening, all lights and fires should be put out, and every one should go to bed. The custom of ringing the curiew-bell about eight o'clock is still kept up in many places, though its original sig-nificance is lost. The law by which it was ordered to be rung was repealed by Henry I., in 1100. The practice of putting out fires so early was highly necessary to prevent accidents, at a time when hearths were placed in the middle of the floor, under an opening in the roof to allow the smoke to escape. This hole was covered up when the family retired to bed. A prayerbell is often rung about eight o'clock in some Protestant countries. This custom arose out of the curfew-bell. Pope John XXXIII., fearing the approach of misfortunes, ordered that every one, on hearing the curfew, should repeat three Ave Marias. The practice of ringing the curiew-bell existed on the continent long before the Norman conquest.

CURIA, ku'-re- $\bar{u}$  (Lat.), signifies both a division of the Roman people and the place of assembly for such a division. Each of the three ancient Romulian tribes, the Rannes, Tities, and Luceres, was subdivided into ten curiæ. The plebeians had no connection with the curie, and the clients of the patricisus were members of the curie only in a passive sense: thus the curie alone contained those that were real citizens, and their assembly alone was the legitimate representative of the whole people. Each curia had its own place of worship, which was superintended by a priest, curio, who was assisted by another, called curialis flames. The word curia is also used to designate the place in which the senate held its meetings; as, curia Hostilis, curia Julis

curia Pompeii, &c.

CURIA, in Arch., the building in which the higher council of the state met, in a Greek or Latin city. It is described by Vitravius as being adjacent to the forum. Its form was quadrangular, either equate or oblong. Halfway up each wall there was a projecting shelf, or cornice, to prevent the voice being lost in the height of the building. A sort of religious character was conceived to belong to the senate-house, and there were often statues of the gods placed in it.

were often statues of the gods placed in it.

CURLEW (Numericus arquatus), kur'-lew (Fr. courils
or corticu).—The gen. to which this bird belongs is
characterized by a long, stender, incurred bill, shightly
compressed and furrowed for three-fourths of its entirelength; it has a blunt fip; wings ample; tarsi naked

above the joints. In length the curlew measures about two feet, and, in the case of the male, the whole planage is bright ash-colour, with longitudinal brown passage is origin assistance, with anogradual brown spots on the head and breast; upper mandible blackish brown; lower mandible flesh-colour; iris brown; feet deep ash. The curlew is very common in most parts of Europe, and occurs in parts of Asia. It inhabits the vicinity of waters and marshy wastes, and feeds on earth-worms, alugs, small testaceans, and insects. Its nest, a careless construction of dried grass and leaves, is usually placed among the rushes. Its eggs are large, ever two and a half inches in length, of an olive-green

colour blotched with deep brown.

Chulling, kertling (Teut. krullen), a common sport among all classes, played upon the ice in Scotland. The sport is regulated by certain rules issued by the Caledonia Curling Club, and artificial shallow pieces of water are maintained for the purpose of playing it. The game is played with flat round stones about 9 inches in dismoster, and about 30 to 45 lbs. in weight. Each stone, deameter, and about 30 to 45 108. In weight. Lean stone, of which every player has a pair, has a handle. A piece of ice is chosen, about 35 yards long and 8 or 9 feet broad, which is called the rink. The players choose sides, and points with circles round them, called tees, are marked off at either end. The number of points restrength of the sides play atternately. The principal object of the curler is to drive his stone towards the tee. Much depends upon throwing it with strength, as well as discretion; for it resary which has obtained a favourable place. The is often necessary to drive away the stone of an adgame is generally played with great keenness. It has of late years been introduced into England and Canada.

CURRANTS, kur'-rants (from Corinth, where they were eriginally grown), the dried fruits of a variety of the grape-vine, now extensively cultivated in Zante and several other of the Greek islands. About 20,000 tons of these minute raisins are annually imported into this country. (See VITIS.) The currents of English gar-dens, red, white, and black, are the produce of species

of Ribes (which see).

CURRENCY, kur-rense (from Lat. curro, I flow or ran), in Pol. Ec., denotes the circulating medium of a sountry, that by which sales and purchases are effected without having recourse to barter. Among savage nations various kinds of articles have been used as a Among savage circulating medium; but as nations became more civilised, the precious metals, particularly gold and silver, came generally to be employed. As trade advanced, however, and commercial transactions became large and frequent, metal money was found to be inconve mient, and recourse was had to a paper currency. this country, then, the currency includes not only the coinage of the realm, but Bank of England notes, and even country bank notes, although not a legal tender,— in fact, whatever passes current from hand to hand, without individual signature, as appears on drafts or cheques. Currency differs from money in so far as it is applied only to what passes as money at a particular time and place. A depreciated currency is a currency which is not equal to its nominal value in bullion. In some parts of Germany, the British West Indies, and North America, the term currency is applied to the moneys of account only. For information as to the paper currency of this country, see BANKING.

CURRENTS, kur'-rents (Lat. currere, to run), the name given to water running in any direction, and, in naviparts of the course in which the water in certain parts of the ocean is always moving, with a constant and generally uniform motion and in the same direcop. These currents greatly tend to accelerate or influence. Two different kinds are to be distinguished -the drift current and the stream current The former is produced by winds which are always ing in the same direction, such as the trade winds or by winds which prevail in certain quarters for con-siderable periods; and the latter by causes about which there seems to be no certain and settled opinion at the present time, but which are probably somewhat analogous to those by which wind currents are proseed in the atmosphere. Ocean currents are of great breedth, and in some cases sweep scross from one consinent to another. In the Atlantic Ocean the great equatorial current crosses from the Gulf of Guines to

the east coast of South America, with a breadth vary ing from 175 to 525 miles and a mean velocity of 14 mile per hour. The Gulf Stream runs from the Gulf of Mexico in a north-easterly direction, and is support to reach the shores of the British isles, being about 3,000 miles long, and having an average breadth of 250 miles. Its waters are of a dark blue colour, and can readily be distinguished from the green waters of the Atlantic. Its mean velocity is about three miles per hour. Its velocity and temperature lessen as it approaches the European coast; the latter being 863 off the American coast, and about 72° where it approaches the continent of Europe. Ref. Maury's Physical Geography of the Sea; Investigations of the Winds and Currents of the Sea; and Charts of the Winds and Currents of the Atlantic.

CUBENCOME, kur'-re-koumb (Aug.-Bax.), a scraper used by grooms in dressing horses. A number of notched iron plates are fixed in parallel lines upon a back-piece about four inches square, to which a handle is attached. The notches form a set of rough teeth,

with which the horse is scrubbed or carried.

CURRY POWDER, or PARTE, kur-ree, a compound much used in India and this country for seasoning a great variety of dishes. It is made by mixing together preserved with various spices; such as coriander-seed powder, black and cayenne pepper, ginger, &c.—Ref. Mrs. Beetou's Book of Household Management.

CURSE OF SCOTLAND, kers, a popular term applied to the nine of diamonds in a pack of playing cards. to the nine of diamonds in a pack of playing-cards. The probable origin of the phrase arose out of the hatred entertained by the Scotch against John Dalrymple, earl of Stair, on account of his connection with the massacre of Glencoe, in which every man under seventy years of age was killed, and as large number of women and children died by cold and hunger. By some reports, the order for the massacre was signed on the large of the part of the massacre. was signed on the back of a nine of diamonds card; but the more probable origin of the phrase consists in the fact that the cont-of-arms borne by Dalrymple was "or, on a ground saltire azure, nine lozenges of the field." The resemblance which these nine lozenges bore to the niue of diamonds probably gave the origin to this strange term. On account of the massacre of Glencoe, Dalrymple had to resign office two years later, in 1695.

CURTAIN, kurt'-n (Lat. curtina), in Mil., the name given to that part of the rampart which is built between the bastions, and, consequently, connects their flanks. The curtain is generally defended by a ravelin or redoubt, and other outworks constructed immediately in front of it, to save it from being too much exposed to the direct fire of the enemy, with whom it is an object to effect a breach in it as soon as possible.

CURTESY. TENANT BY THE, ker'-te-se, -An estate by the curtesy of England is that to which a man is by law entitled or, the death of his wife, in the lands and tenements of which she was seised during the marriage in fee simple or fee tail, provided he had issue by her born alive during the marriage, and capable of inherit-ing her estate; in this case he shall, on the death of his wife, hold the lands for his life as tenant by the curtesy of England. If the lands, however, he in gavelkind, the rule is so far different that he shall hold no more than a moiety, and that only while he lives unmarried; and, on the other hand, his title attaches

whether he had issue born or not.

CURVLE CHAIR (kw'-rule).—A state chair among the
ancient Romans, permission to use which was a mark
of honour, and only granted under the Republic to the dictator, consuls, prætors, censors, chief ædiles, the fismen dialis, and those deputed by the dictator to act under himself. In the times of the Empire this honour was granted to others. The magistrates entitled to use this chair were called curale magistrates, and when they went to council the chair was borne on a chariot (currus); whence its name. At first it was only adorned with ivory, but in later times it was overlaid with gold.

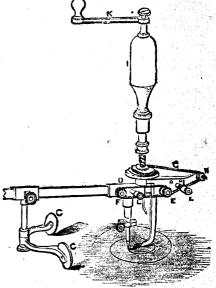

with gold. Curry, kero (Lat. cuspis, a point), in Geom., a line which, running on continually and gradually in all directions, may be cut by a right line in more points than one. The theory of curves forms a very important branch of the higher portion of mathematical science; but only those curves that follow some law

in their change of direction can form the subject of geometrical speculation. The law of the circle is that all portions of the curve are equidistant from one point, called the curve. The invention of defining curves by elgebraic equation is due to Descartes, and the law of a plane curve is generally expressed by an equation between the co-ordinates of any point in it referred to a fixed point. Descartes divided all curves into two classes,—geometrical and mechanical. It is now the outloom to indicate the same distinctions by the terms algebraic and transcendental. The curve is called algebraic when its equation only contains the powers of x and y; and it is called transcendental when the equation contains other functions, such as logarithms of x and y. Algebraic curves are divided into different orders, according to the degree of the equation which expresses the relation between their order, because the equation of a straight line contains no powers or products of the variables x and y. Curves of the second order are those of which the equation rises to two dimensions, and the curves which it includes are the circle, the cllipse, the hyperbola, and the parabola. Out of the infinite number of curves that can be drawn, very few comparatively have received definite names. Besides the four mentioned above, which form the conic sections, there are the semi-cubical parabola, the cissoid of Diocles, the concluid of Nicomedes, the cycloid, the trochoid, the turve of sines, cosines, tangents, &c.; the logarithmic curve and others. Subjoined is a list of the curves that are of usual occurrence: Circle, Ellipse, Hyperbola, Parabola, Semi-cubical Parabola, Cissoid of Diocles, Conchoid of Nicomedes, Triscetrix, Lemniscata, Cycloid, Companion of the Cycloid, Harmonic Curve, Trochoid, Epicrochoid, and Cardioide, Hyporycloid, Epitrochoid, Hyptrechoid, Curves of sines, cosines, tangents, &c.; Exponential or Logarithmic Curve, Spiral of Archimedes, Logarithmie Spiral of Spiral, Litnus Quadratus of Dinostratus, Quadratrix of Tch

CURYES, GEOMETRICAL.—A very valuable instru-ment for the description of geometrical curves has been invented by Mr. Henry Johnson, of Crutched Friars, London. A description of it was read by the Rev. Dr. Booth before the British Association at the Cambridge meeting in the year 1862. The most celebrated geometers of ancient and modern times did not disdain to exercise their ingenuity in the construction of instruments for the graphical description of certain curres by the continuous motion of a tracing-point, and in the actual application of these construc-tions to the manual description of such curres. Nicomedies, the great geometer, who lived two hun-dred years before Christ, invented the curve called the deen years of the calebrated of problem, the depends of the calebrated of problem. the solution of the celebrated old problem, the dupli-cation of the cube. Newton did not think it unworthy his genius to occupy himself in constructing an instrunt for tracing the cissoid by mechanical means. The construction is one of great elegance and simpli-city. In still later times, Sir John Leslie invented a sort of compass to describe mechanically the curve known to mathematicians as the tractrix. Instruments have been invented to describe other geometrical curves; but however ingenious they may be in theory and exact in principle, they are but of little practical value;—they illustrate a principle perhaps, but they do no more. The instrument invented by Mr. Johnson is not a mere philosophical toy, but is designed to meet a requirement and to supply a want that archi-tects and sculptors often experience. An instrument that shall enable architects or others engaged in works of construction to trace with facility the scrolls or volutes of columns, is a help of as much practical value as the tellipic compasses, the protected value as the tellipic compasses, the protector, or the pentagraph. The construction and mode of using the matrament may be thus described :—During the action of the instrument, a bend, a wound round its centre,

603

which regulates the tracing-floint, and thus a continuous curve is described, whose nature will decease on the primary conditions of the instrument. The central spindle may be either a cylinder or a cone, whose vertical angle may be made to vary in say, required proportion. In drawing volutes a flat band may be used, wound round the central cylinder, so that each coil shall lap over the preceding one, and the curve so described will be identical with that which would result from a conical spindle being used. But a grooved cone will be found more convenient, or rather a series of grooved conical spindles, each with a different pitch, according to the curves required. A stand with wheels (OC), moving in a curved horizontal bar, supports the arm of the merable radius (B), which slides through a closely-fitting tube (D) on the stand. To the revolving radius B is fixed a vertical coiled spring. Through the cylindrical or conical spindle of the instrument a steel bar is made to pass, round which (held firmly in the hand by the help of a bollow worden or ivory handle (I), through which it passes), the instrument revolves. One end of a band (G) is attached to the central spindle, while the other is attached at L, passing over

the pulley H. Thus the coiling or uncoiling of the band shortens or clongates the horizontal arm, which is always parallel to the radius vector of the curve. The curves may be described expanding outwards from the central point; or, if the curve be commenced at a certain distance from the centre, it may be described in diminishing spirals until the tracing-point reaches the centre. When the difference between sny two coincident radii of the spiral is required to be less than the circumference of the central cylindrical or conical spindle, the result may be effected by using two sets of pulleys (F and E), one set of which (E) is firmly attached to the stand, while the other (F) is movable, and may be attached snywhere to the sliding horizontal arm. The effect produced varies, of course, with the number of pulleys used; for as the vertical axis of the instrument and the point of the horizontal bar, to which motion is communicated, being consected by a band passing over a system of pulleys, the length of the band becomes 2 times the radius of the apiral (t), being the number of pulleys attached to the block through which the horizontal arm passes.

Hence, by increasing t, the number of pairs of pulleys,

Hence, by increasing t, the number of pairs of pulleys, we may diminish in any ratio we please the width of the apirals described by the instrument.—Ref. Givil Engineer and Architect's Journal, vol. xxvi.
CURVEX, or CORVEX, kerv'-et (Ital. corvetta), in horsemanship, an air in which the horse's legs are more raised than in the demivolt; a leap both up and forwards, wherein the horse raises both his forefeet at once, and as his fore-legs are falling he raises his hind-legs as he did his fore; so that his fore-legs are in the air at the same time.

his hind-legs as the did his tore; so the his hind-legs as the same time.

Cuspo-Cuina (kus-ko).—Three different barks pass under this name, one the produce of Cinchona seroisculata, called in Peru red Cusco bark. The accound appears to be the produce of Cinchona substitute. There is also a third, which is perhaps the white Juen. "The alkaloid is procured by the same white Juen." process as is used for cinchonia, which it resembles in its physical qualities; but differs in its chemical habitudes. The taste is more bitter, rather heating, and sub-astringent. It is equally insoluble in water, but easily soluble in alcohol and sulphuric ether. forms with acids, salts, which resemble those of cin-chonia, but have a more bitter taste. The sul-phate conducts itself very singularly."—English Cyclopædia.

CUSCUTACEE, kus-ku-tai'-se-e, in Bot., the Dodder fam., a small nat. ord. of dicotyledonous plants, which is generally regarded as a subdivision of Convolvulaceæ. The plants composing it are distinguished from those of that order by their parasitic habit, by the absence of leaves, by the tube of the corolla being furnished with scales alternating with the segments, and by having a thread-like coiled embryo with almost obsolete cotyledons. They are chiefly natives of temperate climates, and are often very destructive to flax

slover, and other crops.

Cuse, kusp (Lat. cuspis, a point).-When two curves CUSF, Kasp (Lat. cusps, a point).—When two curves touch, or appear to touch each other, and terminate in a point at which they have a common tangent, this point is called the cusp of the curve. Cusps are of two kinds; in one, the tangent lies on one side of both curves, and their convexities are both turned in the same direction towards the tangent; in the other, the tangent hes between the curves, and their convexities are turned towards the tangent in opposite directions. In Arch, the term is applied to the points formed by the meeting of curves in the interior of trefoils, quatre-foils, &c., and in the ornamental stone tracery of church windows these points are often adorned with foliage. The cusp was introduced towards the close of the first period of Gothic architecture, and became a marked feature in the Decorated English and Perpendicular English styles.

CUSPARIA BARR. (See ANGUSTUBA BARK.) CUSTARD-APPLE. (See ANONA.)

OUSTON. (See IMPRISONMENT.)
CUSTOM, kus'-tom (Fr. continue), in the human economy, differs from habit, with which it is usually coupled, in being a frequent repetition of the same act, whereas habit is the effect which such custom produces upon the mind or body. Custom is well said to be "a second nature." It is able to give a man inclinations and capacities altogether different from those howns born with. Acts that are at first most disagreeable to us, or are only accomplished with the utmost difficulty, become, by each repeated act, more easy and pleasant; until at length it may be difficult, or even impossible, for us to retrain from doing them. Physioloimpossible, for us to retrain from doing them. Physiologiats tell us that every act of the body,—nay, even every thought of the mind,—destroys a certain portion of the natter of our body; but, by that very act of destruction, an increased energy or vitality is communicated to the part, by means of which, in a healthy and natural condition, a larger quantity of fresh matter is attracted to the part, and by this means an increased actors of materials is laid up for future use. By this means the arm of the blacksmith acquires strength; the foot of the dancer and the hand of the musician their deriverity. The effect of custom makes but little figure during the vivioity of youth; in middle age it gains ground, and in old age it governs without control. To introduce an active habit, the mere repetition of acts is not sufficient, without length of time. The acts when the temperature to be sentrated from each other by short in.

## Customs Duties

tervals of time, in order to acquire their full force; and the more regular and uniform any operation is, the sooner it becomes habitual. Some pleasures are strengthened by custom, which in other cases begets familiarity and indifference, or even diagnat. Custom blunts the edge of distress and pain; yet the want of anything to which we have been long accustomed is a kind of torture. The power of custom is a happy contrivance for our good. The mind grows fund of these actions which it is accustomed to; and what was at first difficult and disagreeable, becomes at length easy and pleasant; so that even our employments come to be changed into our diversions. It thus also distributes a corresponding amount of pleasure among all ranks of life; for while it renders pleasant the labours of the poor man, the pleasures of the rich man lose their effects from satiety. Satiety is necessary to check exquisite pleasures, which would otherwise engrous the mind and withdraw it from more important pursuits. From a consideration of the effects of custom we can see the importance of that precept which the heathen pullosopher Pythagoras is said to have given to his disciples,—Optimum vitæ genus eligito, nam consustate faciet jucundissimum—" Select that course of life which is the best, and custom will render it the most pleasant."

pleasant."
Cusrom is a rule of civil conduct prescribed to the inhabitants of this kingdom. The lex non scripta, or unwritten law, includes not only general customs, or the common law, properly so called, but also the particular customs of certain parts of the kingdom, and likewise those purticular luws that are by custom observed only in certain courts, jurisdictions, or among particular bodies of men. General customs are the universal rule of the whole kingdom; purticular customs are rupolabily the remains of a multitude of customs are probably the remains of a multitude of local customs, prevailing, some in one part and some in another, over the whole of England while it was broken into distinct dominions, and out of which, after it became a single kingdom, one common law was soliected and made applicable to the realm at large; but for reasons now long forgotten, particular counties, cities, towns, manors, and lordships, were indulged with the privilege of abiding by their own customs, in contradi tinction to the rest of the nation at large, which privilege is in many justances confirmed to them by charter or by several acts of parliament. Such is the custom of guvelkind, borough-English, of manors, of the city of Loudon and other places; and to this head has been referred that branch of the law which comprises certain rules relative to bills of exchange, partnership, and other mercantile matters, and which is generally denominated the custom of merchants. The validity of a custom is determined by the following rules:-1. It must have been used so long that the memory of man runneth not is the contrary. The time of legal memory runneth not is the contrary. refers to so remote a date as the commencement of the refers to so remote a date as the commencement of use reign of King Richard I.; but the observance of a custom for a long time will amount to presumptice proof of its having prevailed during the whole period of legal memory. The principle is materially qualified by the Statute of Limitations of 2 & 3 Will. IV. c. 71. 2. It must have been continued. Any interruption would cause a temporary ceasing; the revival gives it a new beginning, and thereupon it becomes void. 8. It must have been peaceable, and acquiesced in. 4. It must be reasonable, or rather, taken negatively, it must not be unreasonable. 5. It must be convinced in the transition of the unreasonable. 5. It must be convinced with each other. 8. And customs must be convinced with each other. 8. And customs in derogation of the common law roust be construed strictly. 9. No custom

can prevail against an act of parliament.

Customs Duties are duties charged upon commodities on their being imported into, or exported from a country. They appear to have been called customs from being customary payments, or payments which had been in use from time immemorial. They seem to have existed in every commercial country. The trouble and expense necessarily incurred by a government in making provision for the commerce of a country, naturally led to its seeking some means of remuneration, and none seemed at fair and reasonable as that it should fall on the goods or ressels on whose behalf they were incurred. Customs duties were levied in England require to be separated from each other by short in- previously to the Conquest. It is said that Ethelsed

## Customs Duties

established duties on ships and merchandiae, to be paid at Billingsgate, in the port of London, about 979. In at Ritingsgate, in the port of London, about 579. In 1206 the entire customs revenue of England, including that derived from tolls and fairs, amounted to only £4,638. 7s. 34d. At first, the duties were principally raised on wood, skins, and leather, when exported, and seem considered part of the inheritance of the crown. By an act of 3 Edward I, aduly of 6s. 8d. was teried on every sack of wool containing 26 stone; 6s. 8d. on every 300 woolfels (sheep skins); and 13s. 4d. on every ast (12 dozen) of hides. Foreign merchants paid one half more than English merchants; and a subsequent act of the same reign established certain new customs. to be paid by foreign merchants only. The duties of teninage and poundage were customs duties; the for-mer being paid upon all wine imported, at so much a tun; and the latter, a duty on all goods not specified, at so much in the pound of their value. In the 47th year of Edward 111., a duty of 6d. in the pound was imposed upon all goods exported and imported, except wool, woolfels, leather, and wine, which were subject to particular duties. In the 14th of Richard II., this to particular duties. In the 1stn of Archand Al., dust duty was raised to 1s.; but three years afterwards it was again reduced to 6d. In the 2nd of Henry IV. it was raised to 8d., and in the 4th of the same prince, to 1s. From this time to the 9th of William III., this duty of poundage continued at 1s. The duties or subsidy of tonnage and poundage were granted for the defence of the realm and the keeping and safeguard of the seas, and for the intercourse of merchan-dise, and were at first granted only for a fixed period at the beginning of each reign, but afterwards for life. At the time of the Revolution, in 1688, the customs duties amounted to:-£, s. d. 577,507 12 105

1. Tonnage and poundage 2. Duties on wines and vinegar imported 3. Duties on tobacco and sugar imported 4. Duties on French linens, silks, brandies, &c. ...

172,900 11 04

148,861 8 0 93,710 8 1

£992,980 0 0

The last three classes of duties were imposed in 1685. A new subsidy of poundage, an additional is. in the pound, or 5 per cent., was imposed by the 9 & 10 William III., on most imported commodities. Nemerous additions and alterations were subsequently was a subsequently with the contraction. made on the customs duties, and various modes of rating adopted, so that the simplicity of the ancient plan was destroyed, and eadless confusion produced, In order to remedy these inconveniences, Mr. Pitt, in 1767, proposed the abolition of all duties then subsisting, and the aubstitution, in their stead, of one single duty on each article, amounting, as near as possible, to the aggregate of the various duties then payable. These principles were embodied in the act 27 Geo. 111. c. 13, commonly called the Consolidation Act. In 1803 another consolidation of the duties was effected by 43 Geo. III. c. 68; but numerous fresh enactments having impaired the utility of these arrangements, the government was induced, in 1823, to cause the preparation of a new set of laws for the consolidation of the customs. Mr. Descon Hume, then comptroller of the customs in the port of London, and afterwards secretary to the Board of Trade, was appointed by the Treasury to under-take the preparation of a general law, or set of laws, for the consolidation of the customs of the United Kingdom. The bills prepared by him form the subject of cleven acts of 6 Geo. IV. (c. 106 to 0.116 inclusive), and received neces to cree. 1v. (c. 100 to c. 110 inclusive), and received the royal assent in July, 1825. They came into operation on the lat of January, 1826, and, by their great simplicity, proved of immense advantage to commerce. In 1833 eight of Mr. Hume's acts were repealed or altered by 3 & 4 Will. IV. c. 50 to c. 57 inclusive. In 1843, Sir Rahart Paal' mornared considerable in 1842. pealed or attered by 5 & 2 will. IV. 5, 50 to 5, 5 inclusive. In 1842 Sir Robert Peel proposed considerable improvements, which were carried into effect by 5 & 6 Viot. 6, 47, by which the duty was reduced on 75 different by the truth of the control of the contr entarticles, and the number of articles in the tariff reduced to 818. In 1845 Sir Robert Peel effected still Particle improvement by abosehing the duty on 430 other articles. Since that time, almost every year has seen alterations and improvements in our tariff, and in 1853 the duties on 133 articles were entirely re-

# Cutlery

moved. (See Tariff.) In 4763, the set precises of the customs duties was about £2,000,000; in 1792, £4,47,000; in 1815, £11,360,000; in 1850, £21,054,528; in 1840, £23,466,117; and in 1870, £21,449,843. The amount of duties repealed or reduced in 1860 was £2,840,891, and imposed, £577,904. The collection of the customs duties and the enforcement of the laws the customs duties and the entorcement of the laws which relate to navigation and trade are, subject to the control of the lords of the Treasury, in the hands of a board consisting of a chairman, deputy chairman, and four commissioners; with a secretary, assistantsecretary, and a staff of subordinate officers. As nearly one-third of the entire revenue of the country is derived from the customs duties, they are of the utmost importance to our prosperity, and there are many important questions connected with them. The duties should tant questions connected with them. The ditties should in no case be so high as to encourage sungiting, nor, indeed, in most cases, so as to interfere with their consumption; neither should they in general be too low, for then they must be extended over a great number of articles, by which means the expense of collection is largely increased, and the freedom of the trader much interfered with. They should be levied, as much as possible, on articles that do not constitute as much as possible, on articles that do not constitute. necessaries of life, or necessaries of manufacturing industry. Moderate customs duties are among the least objectionable of all taxes, as they interfere little with the operations of the manufacturer or trader, in many cases serving rather as a protection to the for-mer, and are collected at the least possible expense. With one or two exceptions, where the duty is high on certain necessaries of life, there is little to object to in our present system of customs duties. Down to the time of the Revolution, customs duties were charged indiscriminately on commodities whether exported or imported; but, since that time, they have been almost exclusively laid on imported articles, and now are so entirely.

CUSTOS ROTULORUM, kus'-tos rot-u-lor'-um (Lat.), in Law, is a special officer, who is always a justice of quorum, to whom are committed the records or rolls of the general and quarter sessions of the peace of the county for which he is appointed. His nomination is by the royal sign manual, and to him the nomination of the clerk of the peace belongs, an officer who acts as clerk to the court of quarter sessions, and records all their proceedings, and who also takes the custody of such documents as are directed to be deposited with him by statute, or under the standing orders of either house of parliament.

CUTANEOUS DISEASES. (See SKIN, DISEASES OF THE.)

CUTICLE. (See SKIN.)
CUTLASS, kuti-lis (Fr. contelus), in Mil., a broad heavy sword with a basket-hilt of iron, used by sailors in boarding an enemy's vessel. (See BROADSWORD.)

in boarding an enemy's vessel. (See BBOADSWORD.)
CUTLENY, kut'-ler-e (Fr. contellerie), in a general
sense, includes all cutting instruments, such as knives,
forks, seissors, &c. There are three kinds of steel
employed in the manufacture of different articles of
cutlery,—common steel, shear steel, and cast steel. All
edge tools which require to be tenacious without being very hard, are made of shear steel. The best scissors, razors, penknives, &c., are made from cast steel, which razors, penkinyes, &c., are made from cast steel, which is able to take a very fine polish. Common steel is only used in making very common articles of cutlery. In making good table-knives shear steel and cast steel are generally preferred. In the ordinary method of making knives, the blades are cut out of a sheet of steel, and the backs, shoulders, and tange of wrought iron, are attached to the steel blades by welding at the force. The knife is then ground to the proper share iron, are attached to the steel blades by welding at the forge. The kuife is then ground to the proper shape, and the blade polished and hardened. The fork manufacturers as distinct branch of industry, and the manufacturers of table-knives generally buy their forks from the fork-makers ready to be put into their handles. In muking table-knives two men are generally employed; one is called the foreman, or maker, and the other the atricer. Purpose are usually forced by ployed; one is called the foreman, or maker, and the other the striker. Penknives are usually forged by a single hand, with hammer and anvil simply; they are hardened by heating the blades red-bot, and dipping them into water up to the shoulder. Razors are also hardened in the same manner. The grinding and polishing of cutlery are generally performed by machinery. The business of the grinder is divided into

605

three processes, grisding, glasing, and polishing. Grinding is performed upon stones of various dimensions, those articles which require temper requiring to be ground on wet stones. Glasing is a process by be ground on wet stones. Obssing is a process by which leastre is given to cutley; it is performed with a glazer, consisting of a circular piece of wood, sometimes covered with leather, or an alloy of lead and tin; it is fixed on an axis, like a grindstone. The polishing process is the last, and is performed on a similar piece of wood covered with buff leather. Only articles of east steel which have been hardened and tempered are subjected to this operation. The manufacture of cutsubjected to this operation. The manufacture of cutlery has been brought to great perfection in Great Britain. The principal manufactories are in London and Sheffield.

Three, kut-ter, a small kind of vessel, rigged somewhat like a sloop, fitted with one mast and a very long bowsprit, the latter of which can be reefed, or taken when it is necessary to use a smaller jib. They are employed by government for the revenue service, as the swiftest and most convenient vessels for chasing smngglers, and for preventing the landing of contraband goods. This term is also applied to small clin-

band goods. This term is also applied to small clincher-built boats, used by the officers of ships, similar in shape to gigs, but with sharper bows, having generally six or eight oars. Eight-oared cutters are now much used in regatta-racing.

Cuttle-Fish (Octopus), kut'-tl fish (Ang.-Sax.), a molluseous animal of the gen. Sepia, ord. Cephalopoda. The body is somewhat oval, but broader at the head than at the extremity, which is obtusely pointed. The head is furnished with eight arms and two feet, the head is furnished with eight arms and two feet, the latter being nearly similar in structure to the arms or tentacula, but considerably longer in their dimensions. A neck divides the head from the body, which is furnished on each side, throughout its entire length, with a narrow fin. The back of the cuttle-fish is strengthened by a calcareous plate, well known as the cuttlefish-bone. This bone was in former times in great repute among apothecaries as an absorbent; but now it is chiefly used in the form of a powder, to polish the softer metals. The term bonc, however, is properlinapplicable to the calcareous shield of the cuttle-fish however, is properly as in its composition it is exactly similar to shell, and consists of various membranes hardened by carbonate of lime, without the smallest mixture of phosphate. This animal is sometimes termed the ink-fish, a name that arises from the circumstance that beneath its throat is a bladder, in which is secreted a fluid black as the blackest ink, and which, when annoyed or pur-sued, it ejects, so staining the water around it, that it is an easy matter for it to escape unperceived. its olour, a circumstance that did not escape the cobservation of Mr. Darwin while at the Cape de Verd Islands. "I was much amused by the various arts to Islands. "I was much amused by the various arts to escape detection practised by one individual, which seemed fully aware that I was watching it. Remaining for a time motionless, it would then stealthily advance an inch or two, like a cat after a mouse, sometimes changing its colour. It thus proceeded till, having gained a deeper part, it darted away, a wing a dusly train of ink to hide the hole into which it had crawled." There is a serious belief among fishermen generally that the larger copbalopoda are highly dangerous, from awisting their arms round swimmers, and thus impeding their motions. "Some of these, particularly those of Sicily, are sometimes caught of an enormous size, with their arms fully as long as an ordinary man's leg; but notwithstanding the marrellous stories related and believed by their captors, we did not hear of any well-authenticated instance of these animals having actu-ally occasioned loss of life."—Swainson's Instincts of Animals.

CETTY STOOL, kut'-te, in the Scotch church, was the stool or seat of repentance on which offenders against chastity had to ait during divine service, professing repentance and receiving the minister's rebukes.

CYANIC ACID, si-dn'-ik, in Chem., C, HNO, or CyO, HO,—When cyanogen is passed through a solution of an alkali, a change takes place similar to that which occurs when chlorine is used in the same manner. Granide and cyanate of the base are produced, the

of oxygen, instead of five, as in the case of chingis scid. There are several more convenient methods of pro-ducing cyanic acid than the one named. One is by heating an intimate mixture of two parts of ferrocyanido heating an intimate mixture of two parts of ferrocyanide of potassium with one of peroxide of manganese, the mass being constantly stirred until it reaches a low red heat. When cool, cyanate of potash may be dissolved out. Cyanic acid is so unstable that it cannot be separated from its compounds by an acid. It is best procured by distilling eganuric acid (which see), a crystalline compound having precisely the same composition, in a sealed tube. It is extremely pungent, very volatile, and acts as a powerful caustic if dropped on the flesh. It cannot be preserved, as it gradually changes into a white glassy mass, destitute of acid properties, insoluble in water, and permanent in air. This body has been named cyamelid, and has exactly the same components as hydrated cyanuric and cyanic acids.

CYANITE, ei'-an-ite (Gr. kuanos, blue), a mineral belonging to the garnet family, occurring in broad prisms in mica and tale schists. Transparent cyanite is often used for sapphire; but it may be known by its inferior hardness.

Interior hardness. CYANOGEN, si-dn'-o-jen (Gr. kuanos, blue, and gennao, I produce), in Chem., symbol Cyor NC<sub>2</sub>, equivalent 28, spec. grav. 1'8064, combining volume 2.—Cyanogen, or bicarbide of nitrogen, is one of the most interesting of the carbon compounds, its discovery by Gay-Lussac in 1814 having thrown considerable light upon two important facts in chemical science,-the existence of compounds acting as elements, and of substances having the same ultimate composition, but different properties. In fact, it was the means of originating new theories with respect to organic bodies generally. eyanogen, signifying blue-producer, was bestowed on this substance in consequence of its forming an essential ingredient in Prussian blue. Cyanogen cannot be formed by the direct union of its elements, but may be obtained by passing nitrogen over a mixture of charcoal and carbonate of potash heated to redness in a porcelain tube. The potash becomes reduced to po-tassium, carbonic oxide escapes, and cyanogen is formed, which unites with the potassium, yielding cyanide of potassium. The reaction that takes place is interesting-

## $KO_{1}CO_{2} + C_{4} + N = K_{1}NC_{2} + 3CO_{2}$

The compounds of cravegen are, however, generally obtained from the ferroevanide of potassium, a salt formed by heating in a covered pot five parts of refuse animal matter, such as hide, hoof, and horn waste, with two parts of potash and iron filings. The mass, when cold, is digested in water, which dissolves out the when cold, is digested in water, which dissolves out the ferrogrande of potassium. Ten parts of this salt, distilled with seven parts of oil of vitriol and five or six parts of water, yield hydrocyanic or prussic acid, which, if saturated with oxide of mercury, furnishes cyanide of mercury. This, on being dried and heated in a retort, furnishes eyanogen. Cyanogen is a colour-In a retort, turnishes evanogen. Cyanogen is a colour-less gas, with a peculiar penetrating odour. It is poisonous in its effects if breathed, and it burns with a beautiful purple flame. It dissolves in one-fourth of its bulk of water, in one-twenty-lifth of sleohol, and may be submitted to a high temperature without de-composition. It is easily liquefied by a pressure of four atmospheres. In the liquid state it is colourless, limpid, and lighter than water. At -3° Fahr, it freezes furnand lighter than water. At -3° Fahr, it freezes, forming a transparent crystalline solid. Cyanogen, which is in itself a compound radicle, has the property of uniting with various elements to form still more complicated radicles. Thus, with iron it forms two compounds,—ferrocyanogen, FeCy,, or Fey, and ferrilyanogen, FeCy, or FeY, and ferrilyanogen; FeCy, or FeY, and ferrilyanogen; with manganese, mangani-cyanogen; with platinum, platino-cyanogen; with palladium, palladio-cyanogen; with iridium, iridio-cyanogen; and with copper, cupro-cyanogen; which all behave as elements, uniting with the metals and forming hydracids with hydrogen. The principal compound of cyanogen is cyanic acid, composed of an equivalent of cyanogen and an equivalent of cyanogen are an equivalent of cyanogen described under the head of Cyanogen Acid. It also forms five other compounds with oxygen. is in itself a compound radicle, has the property of nide and cyanate of the base are produced, the ACID. It also forms five other compounds with oxy-ic acid, however, containing only one equivalent gen, all of which possess previsely the same composition, but differ remarkably in their properties. They are cyannic, cyanilo, fulminuric, fulminic acids, and a body called cyametid. Descriptions of their properties will be found under their respective headings; with nitrogen, cyanogen forms cyanamids, which has been already described. Cyanogen forms with chlorine three compounds, which all have the same ultimate composition, but differ materially in their properties. One of them is gaseous, another liquid, and the third solid. With iodine and bromine it forms solid combinations: with sulburn it forms a it forms solid combinations; with sulphur it forms a compound radicle, sulpho-cyanogen (Scy), which, with hydrogen, forms hydrosulpho-cyanic acid; with selentum a similar compound is formed. The cyanides of the alkalies and earths are soluble; those of the heavy metals mostly insoluble in water. The most impact of the control o portant of these is the cyanide of polassium, which is obtained by heating to redness in an iron crucible eight parts of ferrocyanide of potassium and three of carbonate of soda, until the mixture has ceased to be of a yellow colour, and has given off the last bubble of This salt is made in large quantities for the use of electrotypists and photographers. The former use it as a solvent for gold and silver in electro-plating; the latter to remove the unused iodide of silver from the collodion-plate. Cyanogen is prone to form double salts with the metals. Cyanide of potassium, when added to solutions of the heavy metals, throws down a precipitate, which is soluble in an excess of the precipitant, forming a double eyanide of potassium and the double cyanides are of two classes These those which form salts easily decomposed by hydrochloric acid, such as cyanide of potassium and silver; and those which are not so easily decomposed, such as the cyanides of potassium and iron, of potassium and cobalt, and several others. The salts of the second class are looked upon by chemists as containing the metal united with the cyanogen, forming an organic radicle. This will, perhaps, be better understood by considering the following formula:-

1st class .- Double cyanide of nickel and potassium, NiCy, KCy.

2nd class .- Double cyanide of iron and potassium, or ferrocyanide of potassium

$$2(KCy) + FeCy = K_2 + FeCy_s$$

Cyanide of potassium. Cyanide of iron. Potassium. Ferrocyanugen

In the latter salts the heavy metal is generally masked; thus the iron in ferrocyanide of potassium is not dis-tinguishable by the usual tests for that metal. The whole theory of cyanogen and its compounds is most intricate and cannot be entered into here. Those who wish to pursue the subject further are referred to the discussion of the properties of cyanogen and its com-pounds, in the third volume of Miller's Elements of Chemistry. When binoxide of nitrogen is passed through a solution of hydro-ferrideyanic acid, a decomposition takes place, an equivalent of hydrocyanic acid being replaced by an equivalent of binoxide of nitrogen. The compounds formed by this radicle will be described under the head of Nigro-Prussipes.

CYANOSIS, OF BLUE DISEASE, si-an-o'-sis (Gr. kuanos, blue), is a diseased condition of the system, arising from a malformation of the heart, which, allowing the intermixing of the venous with the arterial blood, in consequence of which the former is not properly oxygenized, and a blueness is imparted to the skin: whence the disease takes ita name. Little can be done towards effectig a cure of this disease; and though it interferes with the functions of the body and produces

general weakness, it does not necessarily destroy life.
CYANURIC ACID, si-du'-u-rik, in Chem.—This acid is
obtained in a variety of ways, which need not be desoribed here. It is deposited from its aqueous solution

scribed here. It is deposited from its aqueous solution in colourless rhombic prisms. It is sparingly soluble in cold water, more freely in bolling alcohol, and still more so in bolling water. It is polymerio with cyanic acid and several other products of cyanogen.

CYCADACUE, si-ki-dai'-se-e, in Bot, the Cycas fam, a nat. ord of dicotyledonous plants, in the sub-class Gynthospermia, consisting of small palm-like nn-branched trees or shrubs, with stems marked by the cars of fallen leaves. In a few species the seed divides in a forked or dichotomous manner. The

leaves are clustered at the summit, are purallel-veined, hard, and usually decimate in tion. The flowers are quite naked, unisers diccious; the male flowers in cone scales, from the under surface of which one-santhers arise; the female, consisting of maked oplaced on the margins of altered leaves, or of or arising from the base of flat scales, or from the under surface of peltate ones. The seeds are hard or suc-culent, with embryos, single or many, in fleshy or mealy albumen. The plants are principally natives of the temperate and tropical parts of America and Asia and are also found occasionally at the Cape of Good Hope, in Madagascar, and Australia. Their stems and seeds yield mucilage and starch. The product known as Japan sago is said to be obtained from a species of the typical gen. Cycas. This sago is not an article of European commerce.

CYCADITES, si'-ka-dites, in Geol., fossil plants of the colite and chalk, apparently allied to the existing Cycadacea. The leaves only are known.

CYCLE, si'-kl (Gr. kuklos, a circle), in Chron, the name given to any period of time, or a certain number of years, in which certain events and phenomena recur at intervals, in the same regular order of auccession. coming exactly to the same point again at the same time, or very nearly so, at the commencement of each cycle. These divisions are antificial or arbitrary, and have been invented to compensate for the impossibility of measuring natural cycles, such as the revolution of the earth round the sun, or that of the moon round the earth, by our divisions and subdivisions of time. An explanation of the most remarkable of these cycles, and those in common use, will be found under their respective names. (See Calippic Cycle, Golden Number, Indiction, Julian Period, Meronic NUMBER, INDICTION, CYCLE, SOLAR CYCLE.)

CYCLOPEADIA. (See ENCYCLOPEDIA.)

CYCLOPEAN ARCHITECTURE, si-klo'-pe-an (Gr. ku-klops, round-eyed, from kuklor, a circle, and ops, an eye-sion applied to any wall that is formed of large, irregular, unhewn stones, piled together without mortar or cement of any kind. Walls of this without mortar or cement of any kind. Walls of this description are to be seen at Tryus, Mycene, and Epirus, in Greece, that were most probably built by the ancient Pelasgi; and similar specimens of building, though not on the same gigantic scale, exist in Italy, Asia Minor, and Peru, as well as in some parts of the British isles; among which may be mentioned the Laws, near Dundee, in Scotland, and the Giant's Sconce, near Coleraine, in Ireland. The name was given to walls of this kind because they were supposed to have been built by the Cyclopes, one-eyed giants, who were the workmen of Vulcan.

CYDONIA, \*\*i-do'-ne-d (so named because a native of Kydon, in the island of Crete), in Bot., the Quince, a gen. of plants belonging

to the nat. ord. Rosaceæ and sub-ord. Pomeæ. C. vulgaris is a deformed low tree, sometimes cultivated for its fruit, which is a pome with a persistent calyx, like the medlar. This fruit is mixed with apples in making pies and tarts, and is much esteemed for the preparation of a kind of marmalade. In the rind of the quince Wohler has tound cenanthic ether, to which its peculiar fra-

which its pecuniar irangrance is due. The seeda contain much mucilage and are occasionally used for preparing bandoline (which see).

CYGNET, (See SWAR.)

CYGNET. (See SWAR.)

CYGNUS, sig/ones (Lut. cygnus, a swan), a constellation in the northern hemisphere, situated between those of Cassiopeis and Lyra. Its brightest star is one of the second magnitude.

CYLINDER, sil/-in-der (Gr. kulinde, I roll), a solid body which has three surfaces, one of which is convex and continuous, and the other two parallel. A right cylinder is one in wifich the line joining the centres of

## Cylinder of a Steam-engine

the limiting ourcles is perpendicular to their plane. All other cylinders are oblique. A right cylinder, taken in this view, may be conceived as described by a rectangular parallelogram, revolving about one of its sides. Criticipies of a Strain-weight is that part of the engine in which the piston works, and from which, by alternately admitting and condensing the steam, all the power, of the machine is derived. The boring of cylinders for steam-engines requires very powerful and securate machinery. The cylinder is cast hollow, and the object of the boring-machine is to produce a true cylinder, with an even surface, so that the piston may fit exactly and work freely. Some machines for this purpose sot horizontally and others vertically, while the unitees receive and advance by the action of some powerful prime mover. This operation is generally repeated three times, in the last of which the greatest powerful prime mover. This operation is generally repeated three times, in the last of which the greatest care is required.
CXMA RECTA, si'-mā rek'-tā (Lat. cyma, a little ahoot,

a branch; recta, right), in Arch., the name given to a moulding which somewhat resembles the letter S, thollow in the upper part and projecting below. When this order is changed, and the projection is above instead of below, the moulding is called cyma reversa. The entire curve which a section of the moulding presents will be found to consist of the conjunction of two parts, each of which is exactly one-fourth of the

circumference of a circle.

CXMATUM, sim-ai'-she-um, the upper part of the cormoe of an entablature (see Cornice, Entabla-TURE); so called because it is generally in the form of the moulding described in the preceding article

CYMBALS, sim'-bale (Lat. cymbalum), musical instruments, the origin of which is very ancient,—indeed, probably more so than that of the tambourine. They were made of sourcous brass or copper, and were very various in form; the difference consisting in the size, the presence or absence of a rim, the depth or shallowness of the bowl, as well as the shape of the handle by which they were held. Modern cymbuls are, parexocllence, military instruments; and, when played with taste, form a very pretty addition to a band. They are instruments of percussion; and, when struck together, produce a loud harsh tone of no fixed pitch. The best cymbals are obtained from China and Turkey; and all the attempts of Europeans to discover the metal of which they are made have hitherto proved abortive. Although best adapted for military bands, modern composers often introduce them in the orchester with the metal of the composers of

tra with very pleasing effects.

Crack, sime (Gr. kuma, a spront), in Bot., a common term for the different kinds of definite inflorescence; that is to say, for every inflorescence formed of a terminal flower, beneath which are lateral branches, each having a terminal flower, and lateral branches again similarly dividing, and so on. The varieties of the cyme will be described under the head of Invic-

RESCENCE.

CYNARA, sin-ai'-ra (from Gr. kuon, a dog, in allusion

to the spines of the involucrum), in Bot., a ger, of plants belonging to the nat. ord. Composita: It includes the artichole and cardoon (which see).

Others, sin'-iks, the name of a sect of ancient phicosphers, whose founder was Antisthenes, a disciple of Sagrites. According to some, the name is derived from the Greek word kuon, a dog, on account of the anaring character of the sect; according to others, is is formed from Cynosarges, the name of the gymnatium in which the founder expounded his system. His debutrines were chiefly confined to morals, and, like most other moral systems, in attempting to re-form certain evil tendencies he fell into their opposite form certain evil tendencies he fell into their opposite extremes,—in avoiding Scylla he fell into Charybdis. The evils resulting from the refinement and luxury of his age having attracted his notice, he attempted to lead men back to their original simplicity of life and manners. He taught that the true dignity of man consists in wisdom, and wisdom in independence of mind; and being by thirth poor, and, consequently, excluded from all political rights, he maintained that this independence or, rather, freedom from all restraint, was to be attained by man rendering his wants as few and to be a transmitted to the compoundance. It differs in occupion at women and or disciple of Scorates, heing Aramania heing his col

# Cyrenalos

the garb and the staff and wallet of a mendicant. is represented as teaching that pais or lawour, and even infamy, is a good, and pleasure, on the contrary, an evil. His doctrine of the supreme good is a life secording to virtue, which consists in action, and rean evil. His doctrine of the supreme good is a superacording to virtue, which consists in action, and requires neither many words nor extensive knowledge. He condemned all civil institutions, despised the fees of kin or country, and saw in wedlock no higher us better end than the propagation of the species. These peculiar views were carried to still greater lengths by his followers. With them philosophy was considered to consist entirely in practice, in the srt of living, or in the attainment of a pleasant life, which consisted solely in dispensing with all, even the most simple and necessary wants. The sage, they maintained, ought to be free from all outward influences, and superior to all the accidents of chance or change. Most of the arts and sciences, as they do not tend to make men virtuous, but sometimes, on the contrary, interfere with the attainment of it, are unprofitable and permicious. The most famous of the Cynics besides their founder were Diogenes of Simope, Crates of Thebes with his wife Hipparchia, and Menippus. At length the sect became so disgusting from their impudence, dirty habits, and profligacy, that they ceased to be rethe sect became so disgusting from their imputence, dirty habits, and profligacy, that they ceased to be regarded with any respect, and passed into obscurity. The great merit of this system is that it paved the way for the establishment of Stoicism, by which it was succeeded and superseded.—Ref. Ritter's Geschichte der Philosophie; Hegel's Geschichte der Philosophie; Lewes's History of Philosophy.

CYPERACEE, si-per-ai-se-e, in Rot., the Sedge fam.

s nat, ord, of monocotyledonous plants in the sub-class Glumacea, consisting of grass-like or rush-like herbs, natives of all parts of the world, and found especially in marshes, ditches, and the neighbourhood of running streams. The stems are solid, often angular, and are without joints or diaphragms. The leaves form entire without joints or disphragms. The leaves form entire or closed tubular sheaths round the stem. The flowers are spiked, imbricated, and either perfect or unisexual, each arising from the axil, of from one to three bracts or glumes. The lowermost glumes are frequently empty, or without flowers in their axils. There is seldou a visible perianth; but it exists sometimes in the female flowers as a tube, or as a whorl of hypogynous scales or bristles. Stamens bypogynous, 1commonly 3; anthers 2-celled, innate; ovary 1-celled, superior, with one erect ovule; fruit indebiscent, with a single seed having fleshy or mealy albumen, inclosing a lenticular embryo. Although closely allied to the Graminacea (grasses), the plants of this order are of little use to man, their seeds being deficient in those nutritive qualities which render the seeds of the cerepis so valuable. The rhizomes, tubers, or corms, of some species of the typical genus Cyperus were formerly employed in medicine as aromatic tonics and astriugents. When boiled or rousted, some of these corms are edible.

Ox-Rais, se-prai' (Nor.).—It is a rule with respect to all charities, that the intention of the donor, so far as it is practicable and legal, shall be strictly observed, the law not permitting it to be varied without necessity, even by consent of his heir. But where it is incapable of heine literally actions. of being literally acted upon, or its literal performance would be unreasonable, a decree will be made by the court of Chancery for its execution cy-près, that is, in some method conformable to the general object, and adhering as closely as possible to the specific design of the donor.

CYPSELA, sip'-se-lä, in Bot., the name given to a kind of fruit which occurs in all plants of the order Com-positae. It differs in nothing essential from the achanium (which see), except in being inferior and of

ought to control circumstances, and not to be controlled by thems. According to him, the sum of life was made up of pleasure and pain; the one to be sought after as good, the other to be avoided as evil. The ohief good, according to him, was the greatest number of agreeable perceptions; and the true philosopher was one who actively and successfully pursued pleasure. He taught that man ought to devote himself entirely to the enjoyment of the present moment, either regretting the past nor caring for the futures. Every act was regarded to be in itself morally indifferent, and only to be viewed as it produced pleasure or pain to the individual. The chief successors of Aristippus were Theodorus, Hegesias, and Annicerie, each of whom became the founder of a sect known respectively as the Theodoran, Hogesian, and Annicerian ively as the Theodoran, Hegesian, and Annicerian schools. As Cynicism was the forerunner of Stoicism,

schools. As Cynicism was the forerunner of Stoicism, so Cyrenaism, which constitutes its chief merit.—Ref. Ritter's Geschichte der Philosophie; Hegel's Geschichte der Philosophie; Lewc's History of Philosophie.

CYRILLACKER, si-ri-lai-se-e (in honour of Cyrillo, a Neapolitan botanist), in Bot., the Cyrillo fam., a small nat. ord. of dicotyledonous plants in the sub-class Thalamifora, consisting of evergreen shrubs with alternate extipulate leaves, nearly related to Olsacca, but distinguished by their imbricate petals, which are altogether free from haviness on the inside, and by the stamens being all fertile, and, if equal in number the stamens being all fertile, and, if equal in number to the petals, alternate with them. They are natives of North America; but nothing is known of their

properties and uses.

Crst, sist (Gr. kustis, a bladder), in Anat., is applied to the urinary bladder, gall-bladder, and similar vessels in the human body; but it is also applied to mornid growths within the body, having the form of a bag or

bladder, and inclosing morbid matter.

bladder, and inclosing morbid matter.

CYPINACHES, si-in-ai-se-s, in Bot., the Cistus-rape fam., a small nat. ord. of dicotyledonous plants in the sub-class Monochlamydex, consisting of root-parasites of a fungoid texture. The flowers are perfect or unisexual, and either solitary and sessile or clustered at the top of a sealy stem. Calyx 3—6-parted; anthers sessile, opening longitudinally; ovary 1-celled, inferior; cyclic every numerous; placentas parietal; fruit 1-celled, with numerous seeds imbedded in pulp. The plants of this order occur in the south of Europe and Africa, growing as parasites upon the roots of Cistus, upon fleshy Euphorbiucea, and upon other succulent plants. Some have astringent properties; as Cytinus Hypocistus, from which an extract is made in the south of Europe, and there used in diarrhoss and for arresting his morrhage. Hydnora africana has a putrid animal odour; but when rousted, it is caten by the natives of Africa.

CYTISUS, si'-tis-us, in Bot., a gen. of leguminous trees and shrubs, of which the laburnums are well-known and universally admired examples. The timber of the tree-laburnum (C. alpinus) is much prized by cabinet-makers and turners for its hardness, beauty of wine and depublish.

grain, and durability.

CYTTABIA, sit-tai-re-a, in Bot., a gen. of fungi. C. Darwinii and Berteroi are employed for food; the former in Terra del Fuego and the latter in Chili.

Czan, zar, a title of the emperor of Russia. Up to the 16th century, the principal rulers of the Russian provinces were called grand-dukes. Several adopted the title czar; but Ivan II. Wassiljewitch the Cruel, was the first who was solemnly crowned czar. After him, all the monarchs of Russia called themselves czars of Moscow; and after the conquest of Little Russia and Smolensk, they took the title of czars of all the Russias. The rank of imperial dignity was not granted to the czar by the European powers until the reign of Peter I. He called himself Imperator, and the empress Imperatizs. The ordinary title of the empress is czarina. The emperor Paul I., in 1799, gave the title Cæsarewitch to his second son. All the sons of the czar are

which is the same as the Latin, is evidently de from the Greek (Δ), by rounding off the right angle into a curve. The Hebrew deleta signifi-door, and in its earlier form it bore a manifest r blance to the door or opening of a tent. D is the dial letter of the order of dentals or paleto-der and readily interchanges with those of the same of as German tief, deep; traum, dream; du, thou; de thine. It also readily interchanges with the letter 3; Greek dapsiles, Latin lapsilis: Latin canda, Spanish cola. (See L.) The Latin D is frequently changed into a. s. or ss in German; as duo, cwei, two; decem, zan, ten, D also seems to manifest a kind of affinity for the letter n, and is drawn by it into a number of words to which it does not radically belong; as Latin tener, English tender. Di followed by a vowel is sometimes changed into j; as, diurnal, journal. D, or as is was formerly written, 10, stands for 500. In Music, D is the second note of the diatonic scale, answering to the re of the Italians.

DAB, did (Pleuronectes limanda), a common flat flat well known in the London market. Its average size is eight or nine inches in length, and six or aven in breadth. Its upper side is pale brown, and its under-parts white. It is usually caught with plaice and flounders. The three spring months constitute its "season."

DABCHICK, dib'-tshik, or little grebe (Podiceps minor), a small bird nine or ten inches in length, comminor), a small ord time or ten manes in length, some monly found about lakes and fishpoulds. It is an ex-ceedingly active swimmer, and dives with great ease. It progresses under water with considerable rapidity, with the aid of both wings and feet. The larger greates do not appear to use their wings in this way. (See

DA CAPO, or D.C., da-ka'-po (Ital.), in Mus., an ex-pression placed at the end of a piece, to indicate that the performer is to return to, and end with the first

Dack, dais (Du. daas) (Cyprinus leuciscus), a small, fish found in clear and quiet streams. Its head is small, muzzle pointed; back flightly elevated, and tail slightly

forked. The scales of the dace are rather small. It is gregarious. The food is worms and other soft animal substances. April and May are the prime times to fish for dace.

DACHYDIUM, dă-krid'-i-um (Gr.dukru, a tear), in Bot., a gen. of plants belonging to the nat. ord. Turquez, or Yew family. It includes several valuable timber trees; as, the Huon pine of Australia (D. Frunklinti), the Kakaterro of New Zealand (D. taxifolium), and the

Dimon pine (D. cupressinum).

Dictyl, ddk'-til (Gr. daktulos, a finger), in Greek and Latin poetry, is the name of a foot or measure consisting of a long and two short syllables,—as in calmina, omnibus. It is so called from its resemblance to a finger, which has a long and two short joints. Dactylic verses are hexameters which end in a dactyl instead of a spondee

instead of a spondee.

Dactilis, ddk'-til-is (Gr. daktulos, a finger), in Rot, a gen. of Grasses. The species D. caspitosa, is the tusse-grass of the Falkland Islands, which forms an excellent kind of fodder for cattle. It is now grown to some extent in Shetland and other parts of Britain.

Dactilology, dik-til-ol'-o-je (Gr. daktulos, a finger, and a of discoursing a mode of discoursing the state of the s

D is the fourth letter of our, as well as of the Latin, Greek, and Hebrew alphabets. The Greek name is delta, the Hebrew daleth; and our form of the letter, of a cube,—whence its name. In the internal decora-

tion of buildings, the term is eften applied to the boarding or panelling which covers the lower part of the walls of a room, finished by the skirring-board below, and an impost, or small projecting cornice, called a chair-rail, above. The dado of a room, including its three parts, is about three feet in height. It is commonly found in houses of the 17th and 18th centuries; but it is not much used in the present day.

Danus, in Chem., a hydrocarbon obtained by heating oil of turpentine with quicklime. It is a liquid oil, boiling at 273° Fahr. It is also called comphilene and

camphene.

DERION. (See DEMON.)

DAM, dig (Fr. dague), the name of a hand-gun or pistol, invented in the early part of the 16th century, resembling the demi-haque and pistol in form, but having the butt straight and flat, and terminating in a square surface instead of being curved and flushed by a rounded knob like that of the pistol. The butt, in-deed, was very much like the haudle of a Turkish yata-ghan; or old-fashioned dagger, square and broad where the little finger grasps the hilt, and from this resem-blance the weapon probably derives its name. The Italian for wood-kuife or dagger, is pistolese, which seems to corroborate the supposition that these weapons derived their names from their resemblance to daggers, or from bearing the same relation to a musket that a

dagger bears to a sword.

Dagger, dig-ger (Fr. dagne), a weapon consisting of a short blade, sometimes broad, two-edged, and tapering to a point, and sometimes triangular in form, like a bayonet, set in a hilt, with a loop of wire projecting from it on either side, to receive the pressure of the hand in making a thrust. It was sometimes used as a nand in maxing a turust. It was sometimes used as a wespon of defence, particularly in duelling and single combat, being used in the left hand to parry the thrusts of a rapier. In the days of chivalry, the knight gene-rally carried a long sharp dager in his girdle, called a misericorde, with which be dispatched his adversary when he had unborsed him, if he refused to yield, by

stabbing him in the throat.

Dagon, dai gon (Heb. dag, a fish), the name of a celebrated god of the Philistines, worshipped at Ashdod, Gaza, and elsewhere. Difference of opinion exists as to the form of this idol; but the most general opinion is, that it had the head and hands of a man, while in the lower part it resembled a fish. The form of the figure alludes to the maritime position and piscatorial purshits of the Philistines. Some derive the name from the Hebrew dagan, corp, and believe him to have been the god of agriculture. In 1 Samuelv., we have an ac-count of the fall and destruction of this idol before the

ark of the Lord.

DAGUERRKOTYPE PROCESS, di-qair'-o-tipe, a process of photography invented by M. Daguerre, an eminent Rrench chemist, by which images are impressed on a silver plate. A perfectly polished silver plate is exposed in the dark to the vapours of iodine and bromine, by which means a mixture of iodide and bromide of silver, exquisitely sensitive to light, is obtained. The plate is then exposed to the action of the image formed by light in the camera obscura, for a period varying from a few seconds to several minutes, according to the intensity of the light. A latent impression is formed on the film of bromo-icdide of silver, giving this substance the property of combining with the vapour of mercury in those parts where the light has struck. This latent impression is brought out or developed by being exposed for a few seconds to the vapour of mercury in a heated box. On withdrawing the plate, the mercury will be found to have fixed itself to the silver in exact proportion to the effect of the light on the different portions of the image, the deposit being white and brilliant on the lightest portions, more or less grey on those parts constituting the half-tones, and being absent altogether in the deep shadows. It is then washed with a weak solution of hyposulphite of soda, which dissolves out the bromo-lodide of silver, which has remained unaitered by the light. The last process consists in laying on a fine film of metallic gold, by pouring over the plate a solution of the double hypographite of sode and gold or as it is commonly portions of the image, the deposit being white and sulphite of sods and gold, or sel d'or, as it is commonly termed. There are few questions which have given rise to greater controversies amongst chemists than the nature of the daguerreotype image, many supposing

it to be mercury only, others thinking that it is a smalgam of mercury and silver. B is unfortenest that the quantity of material formed is so very minute that it becomes impossible to subject it it analysis Daguerreotypes have been almost entirely superspects reguerreorypes have seen atmost entirely superagided by photographs on paper and glass. The absence of any unpleasant metallic gloss, and the easier multipli-cation of the latter, to say nothing of the process being much simpler, have almost entirely excluded deguerreorypes from public favour. It often happens that damagractures become that daguerrectypes become covered with a crust of sulphide of silver, from the action of the sulphur compounds contained in the coal and gas burnt in our In such cases the daguerreotype should be houses. In such cases the daguerreotype snows we washed, by a competent photographer, with a weak solution of cyanide of potassium, until the objection. able film is removed, when the image will be found to be restored to its pristine brilliancy. The facts just mentioned dictate the necessity of preserving daguer rectypes in air-tight cases, as much as possible away from the mantel-piece, where they are most usually

DARLGREN Gun, dal'-gren, a gun of heavy calibre, invented by and named after an officer belonging to the United States navy. In form it is somewhat similar to the Armstrong gun, although it does not possess the symmetry, power, and lightness of that weapon. The breech is extremely strong, being very much thicker than the breech of an ordinary cannon; while the part between the fruncious and the muzzle is lighter, and contains less metal than a common gun of the same calibre. It is much used in the United States navy, and highly prized by the Americans; but it is inferior to Sir W. Armstrong's beautiful weapon in every respect. It fires shells as well as solid shots.

Darn, due-re', is the name of the ecclesinatical sove-reign of Jupan, who has his capital at Minko.

DAIRY, dair'-e (Aug.-Sax.), a term usually applied to all that is connected with milk and its management on a farm. It is also applied to the place where the milk is kept and converted into butter or cheese. In the successful management of the dairy very much depends upon the quality of the cows and the food with which they are supplied. The construction of the house where the milk is stored, &c., is of the highest importance. It should be situated on a dry spot, somewhat elevated, having, if possible, a northern exposure. high roof and free ventilation are necessary; and the proximity to pig-sties, sewers, or offensive smells, must be avoided. Coolness is essential during the summer, be avoided. Coolness is executed uning the amount and an equable temperature in the winter. As the milk suffers from being agitated or too much cooled before it is set for the croam to rise, the cowhouse should be as near as possible to the dairy. The milk before it is set for the cross to the dairy. The milk should be as near as possible to the dairy. The milk should be brought direct from the cows, without being the context air, if possible. No substances expected to the outer air, if possible. No substances except milk, butter, and newly-made cheese, should ever be allowed to come into a dairy. The floor and shelves, which are generally of stone or slate, should be carefully washed every day, and any spilled milk should be removed immediately. Scrupplous cleanli-ness, indeed, is the first rule in all dairies. After being brought into the dairy, the milk is run into shallow dishes, made of carthenware or oak, lined with lead. The layer of milk run into each vessel should be shallow, in order to promote the formation of cream. The cream removed at the first skimming is the richest and best, For the methods employed in the dairy for converting milk into cheese and butter, see the articles under these heads. In London and other large towns the cows are kept by the dairymen tied in their stalls. They are seldom kept longer than twelve months, being disposed of as soon as their supply of milk does not equal the cost of their feeding.

DAIS, dais (Fr. dais).—In the common acceptation of the word, when we speak of the dais, we mean the resiced flooring at the upper end of a hall, on which the high table stands, and where the most distinguished nigh table stands, and where the most distinguished guests are seated, or the platform on which a throng, or chair of honour, is placed. This also seems to be the meaning of the term when it occurs in the works of old English poets and prose writers. In France it means the campy erected over a raised platform occurred by the campy erected over a raised platform occurred by the campy erected over a raised platform occurred. pied by the sovereign at any reception or public err-monial, as well as the platform itself; and the canopy

narried over the hest or saored wafer, when the priests are bearing it to the hedside of a dying man, is so called. Originally it most probably neant the canopy only, under which a throne, situr, fout, or statue was placed; being next applied to the elavated platform on which such things were placed, and afterwards to any piece of flooring that was higher than the rest.

enined.

DALMATIC, dal-mat'-ik, is the name of a long white gown with sleeves, formerly worn by the Dalmatiaus, and, since the time of Pope Sylvester I., by the deacons of the Boman Catholic church, over the alba and stola. It was formerly also worn by the German

and stoka. It was formerly also worn by the German emperor at the time of his coronation.

Dam, ddm (Germ. dumm), a construction of stone, wood, or earth, erected for the purpose of keeping back a current of water, with the object of giving power by increased head, or for holding back supplies of water for flooding lands, or for rendering the stream above the dam navigable by increased depth. The first hillders of days were the basers whose confirst builders of dams were the beavers, whose constructions of states, clay, and earth, whose constructions of states, clay, and earth, attest their wonderful sagacity. Perhaps the most magnificent work of this kind is that described by Minard. It is in the province of Alicante, in Spain, between two steep mountains, which are in close proximity to each other. The height of this dam is 18th feet; its length 2724 feet; its thickness at top 694 feet. It was erected in 1594, and is used for collecting water to be used for irrigating the vineyards in the neighbourhood.-Ref. Minard's Cours de Construction des Ouvrages qui établissent la Navigation des Rivières et des Canaux, Liège,

DAM, in Law, a boundary or confinement; as to dam up, or dam out, infra damnum suum, within the bounds or limits of a man's own property or jurisdiction.—Bract., ib. 2, c. 37.

DAMAGE, dam'dj (Ang.-Nor.), in Law, signifies, enherally, any hurt or hindrance which a man receives in his estate; but in a particular sense, it is applied to what the jurors are to inquire of and bring in when any action passeth for the plaintiff. (Co. Litt., 257.) Damages are a species of property acquired and lost by suit and judgment of law, and are given to a man by a jury, as a compensation and satisfaction for some injury sustained; as for hattery, false imprisonment slander, trespass, and otherwise. (2 Bl. Com., 438.) (As to the quantum of damages which will carry costs, see Cosrs.) see Costs.)

DANAGE-FEASANT, or FAISANT, dām'-āj faiz'-ānt (Ang.-Nor.), in Liw, is where a stranger's beasts are found in another person's ground without his leave or license (and without the fault of the possessor of the license (and without the fault of the possessor or the close, which may happen from his not repairing his fences in cases where he is bound by law to fence), and there doing damage, by feeding, or otherwise, to the grass, corn, woods, or the like. (2 Danu. Abr. 364; 3 Bl. Com. 7.)

DAMASK, däm'-āsk (from Damascus, where it was originally made), a woven fabric, in which, by particular arrangements of the loom, figures of flowers, basis and others not of a geometrical form are pro-

fraits, and others not of a geometrical form, are pro-duced. The art of damask-weaving remained for a long time a mystery confined to a few places; but since the invention of the Jacquard loom it is extensively employed where stuffs used for dress or house-furnishing require ornament. The flowered ribbons of Coventry and the costly silks and satins of Lyons and Spitalfields are specimens of damack manufacture. The chief seat of the trade is Dunfermline, in Scotland; it is also largely made in England, Ireland, Belgium, Saxony,

Bilesia, and Austria.

Damaserening, or Damascens-work (düm-üs-DAMASCER-WORK (dim-ga-best-ing (Fr. damaguiner), the art of producing a watered or wavy appearance on steel sword-blades, armour, &c., or of inlaying and encrusting steel with gold and silver: This art was originally practised at Damascus, and was introduced into Europe in the 12th

century by the Crusaders, who frequently be Damasone blades, which were celebrated for their ticity, temper, and keepness, with them on their or from the Holy Land. Vertous methods of damase ing were practised; but the most common seem to been those of welding two different kinds of steel and iron, together, or of cutting lines on the sur-face of the steel and filling them with gold or silver, which was either forced into the incised lines and brought on a level with the surface of the steel, or mained in relief above it. When the former med was used, a light pattern, generally in wavy lines, was produced on a dark ground, or vice versa, and the inneproduced on a dark ground, or vec verse, and the unc-tion of the metals caused the pattern to run through the entire thickness of the blade, so that it could not be obliterated even by grinding. The damaskeened steel armour and works of art in this style of the 15th and 16th centuries came chiefly from Misan and Venice. The most beautiful piece of work of this kind that now exists is the shield made by Benvenuto Cellini, which is in the possession of her Majesty. It was formerly the property of Francis I. of France, and was given by him to Henry VIII.

DAME, daim (Lat. domina, a mistress), formerly a title of honour given to high-born ladies, in order to distinguish them from the wives of citizens and the ordinary guish them from the wives of citizens and the ordinary commonalty. The prefix ma was given to the word dame on account of the great courtesy shown to ladies of high rank. Madame, "my lady," was applied to a lady of title; and in France, Notre Dame, our Lady, was applied to the Virgin Mary as a term of veneration and homage. The word dame, in England, is not much used, but in general signifies a married woman. The French word madame is shortened into madam, and

is used in a similar sense.

is used in a similar sense.

Dammara, dim'nm'ri, in Bot., a gen. of coniferens trees, including two remarkable species. D. australia, the kawrie or cowdie pino of New Zealand, furnishes excellent timber for musts and spars, and also yields a gum-resin, which is now largely imported into this country under the names of Australian copal, kawrie gum, and Australian dammar. It is chiefly used in the preparation of varnishes. D. orientalis yields a somewhat similar gum-resin, which is known as Indian demonstration.

Dampen, dam'-per, a term applied to several mechan-ical contrivances. The damper of a furnace or fire-place is a door or valve, which, by rising, falling, sliding, or otherwise, lessens the passage for air, and thus damps or checks the intensity of the combus-The damper of a pianoforte also acts as a check : it is in the form of a small lever, which presses against a string soon after it has begun to sound, and thus stops the vibration. An apparatus which communicates dampness is also called a damper: thus, damping-machines have been invented for the purpose of moistening postage and other stamps,

DANKER, a sub-ord, of Ferns. (See FILICES.) DANCE OF DEATH, dause, a term applied to a certain class of allegorical representations generally dating about the 14th century, and illustrative of the power of death over the human race. In the dark ages of monkish bigotry and superstition, the people were led into a belief that the fear of death was acceptable to the Creator. Hence they seem to have derived one of their principal gratifications in contemplating this necessary termination of humanity, surrounded by ideas of the most horrible and disgusting nature. The representations of skulls and bones on the tombstones of the present day are the remnants of the customs of that time. Gradually, the feeling of the people towards death changed, until it was represented under simpler and more majestic forms. During this transition-state, one of the most favourite emblems of mortality was the Dance of Death. It was a drains performed in or near churches, and consisted of short dialogues be-tween Death and twenty-four or more followers. It originated in Germany, but was afterwards greatly in vogue in France, where it was called la Danse Monders, from St. Macarius, an Egyptian annehorite. Shortly after its introduction into France, pictorial representations of the dance began to be made, and remains of these are to be found and on the in many allege on the these are to be found not only in many places on the continent, but also in Great Britain. The drams was altogether laid aside in the middle of the 18th century,

Daniel, Book of

and the pictures held the chief place of importance. Hitherto they had been placed only in the quiet cloisters of the convents, but now they were exhibited in public, and soon lost their original character. The protection of Death denoing with his victims was departed from by Holbein, who, availing himself of the subject, produced fifty-three distinct subjects for engraving, which he called "Imagines Mortis." The originals are at \$1. Petersburg. \*\*Hef.\* Holbein's Dance of Death, in Bohn's Riestrated Library.

Distourns diseased one of the eight neculiar forms

DANGETTS, din-set, one of the eight peculiar forms of partition-lines recognized by English heralds. It is a zignag line, the indentations of which are of a great

e, and limited to three in number.

DANCING, dan'-ring (Ger. tanzen), is the art of moving in measured steps, or adapting the movements of the body to the sounds of music. There is no account of the origin of the practice of dancing among mankind. It is found to exist among all nations, even the most rude and barbarous. Among the Jews, dancing seems to have formed part of the religious worship on some coexions, as is evident from some passages in the Pasims. The ancient Greeks made the art of dancing into a system, by which the different passions could be powerfully expressed. Homer mentions dancing at entertainments, and Aristotle ranks dancing with poetry. The Spartans compelled their children to practise dancing from the age of five: they were led by men, and sang hymns and songs as they danced. by men, and saig hymne and cope as they danced.
The Pyrinic dance was danced by the Spartan youths;
it was expressive of a sham fight. There were three
kinds of dances among the ancients: military dances,
intended to make the body robust, active, and well
disposed for all the exercises of war; domestic dances,
which had for their objects or was all the descriptions. which had for their object an agreeable and innocent relaxation and amusement; and mediatorial dances, which were in use in explations and sacrifices. The early Christians danced at their religious assemblies, although there is no mention of the practice in the New Testament. At the present day, duncing is a favourite amusement as a social custom and healthful

DANCING MANIA, an epidemic disorder among sus-ceptible subjects, in which imitation is brought about under high excitement. It is closely allied to hysteria, and principally occurs among persons who are desirous of notoriety or sympathy. During the Middle Ages, epidemics of this class were common in Germany; and in Italy they were ascribed to the bite of the tarantula spider. Towards the close of the 14th century, a number of men and women appeared at Air-la-Chapelle, on the festival of St. John, dancing and screaming in a frantic manner in the streets. Many foamed at the mouth, and danced till they fell down insensible; others dashed their brains out against the walls. While dancing, they were unsusceptible of outward impres sions, but were haunted by visions. The epidemic spread over the Low Countries, and bands of wretched The epidemic ignorant people traversed the country, and, excited by wild music, danced themselves into convulsions, singing all the time in derision of the priests. At the beginning of the 17th century, St. Vitus's dance, as it was then called, was on the decline, and it is now only heard of in isolated cases.

DANDRAION. (See TARAXCUM.)
DANDRAION. (See TARAXCUM.)
DANEGELT, dain'-gelt (Sux. Dane, and gelt, money),
was an ancient annual tax of the Anglo-Saxons, levied
for the purpose of defending their coasts against the Danes.

Dane-Lage, or Dane-Law, dain'-law.—After King at Ethandune, a treaty was entered into by which the Thrandune, a treaty was entered into by which the Danes were bound to eracuate the whole kingdom of Wesser, from Somerset to Kent. They were, however, allowed to occupy the greater portion of the cast const of England, including the whole of Northumbria. The portion of territory which they occupied was called Dane-lagh, or Dane-law; because they were not governed by English, but by Danish law. The treaty was concluded in 878 a.D., and was held in force till the Norman conclude.

the Morman conquiest. Many sale was need in lorestill the Morman conquiest. May yet, is the twenty-seventh in order of the books of the Old Testament, and is the work of the author whose name it bears, at that time acceptive in Babylon, to which country he was taken

when very young. Being of noble, if not of royal extraction, and a youth of great promise, he was brought into the king's court, and instructed in the lan-guage and sciences of the Chaldeans, and subsequently guage and sciences of the Unantesns, and subsequently rose to very great eminence. The book which bests his name is partly historical and partly prophetloal. The first six chapters are historical, and speak of Daniel in the third person; the last six contain visious, which Daniel relates in the first person. In the first six Chapter we have about the contain visious, six chapters we have recorded a variety of events which occurred in the reigns of Nebuchaduezzar, Belshazzar, and Darius; and, in particular, the second chapter contains Nebuchadnezzar's prophetic dream concerning the four great successive monarchies, and the ever-lasting kingdom of the Messiah, which dream God enabled Daniel to interpret. In the last six chapters we have a series of prophecies, revealed at different times, and extending from the days of Daniel to the general resurrection. The Assyrian, the Persian, the Grecian, and the Ruman amiles, we all particularly assembled and the Roman empires, are all particularly described under appropriate characters; and it is expressly declared that the last of them was to be divided into ten lesser kingdoms; the time at which Christ was to appear is precisely fixed; the rise and fall of Anti-christ, and the duration of his power, are exactly determined; and the future restoration of the Jews, the victory of Christ over all his enemies, and the universal prevalence of true religion, are distinctly foretold as being to precede the consummation of all things. The book abounds with the most exalted sentiments of piety and devout gratitude; its style is simple, clear, and concise; and many of its prophecies are delivered in terms so plain and circumstantial, that many have been led to deny their authenticity, and to maintain they were written after the events had taken place. Porphyry, in the 3rd century, affirmed that the book was composed as recently as the time of Antiochus Epiphanes, and that therefore it narrated only past events; and he has had many followers in more recent times, and even in the present day. The arguments, however, advanced against the authenticity or genuineness of the book are of the most weak and frivolous character. "If the book had been written after the events, as these assert, it must have been written in Palestine; in which case the writer would not have been acquainted with the names of the Chaldean offices, which are in the Zendic, Phelvic, and Parsic languages; and he would not have been acquainted with the views peculiar to the Magians, much less would he have ventured to make use of them; he would not have applied to the lack king of the Chaldeans the name Belshazzar, which is unknown to historians; he would not have covered the walls of the royal supper-hall with plaster, but rather with costly wainscot; he not have known that Xerxes had excited even the West (the Carthaginians); neither would he have been acquainted with the history of Alexander, of Egypt, and of Syria (Dan. xi. 2, vii. 6, viii. 5, xi. 3), he would not have mentioned the third expedition of he would not have mentioned the tuird expedition of anticohus Epiphanes a second time (xi. 40) out of its natural order; neither would he have written occasionally so enigmatically, nor have used two dialects, but he would carefully have avoided whatever would have thrown difficulties in the way of his reader; he would not have specified the year and day of his visions, which could afford him no advantage in the transformation of history into a prophage; he would have inserted. ation of history into prophecy; he would have inserted in his visions less of Alexander and more respecting the Maccabees; and he would not have said, in viii. 15, 27, xii. 4, 8, that these predictions were unintelligible until they should be accomplished, and that the prophecy, x. I, was understood by Daniel, such observa-tions being inconsistent with the supposed transform-ation."—(Jahn's Introduction to the Old Testament.) In short, the book is exactly such as one living at the time, and in the circumstances of Daniel, would have written, and is as different as possible from anything that we could conceive written during the Maccabeau period. The very accuracy of these prophecies, which is objected to their authenticity, is what might be expected from a man of his character, as a man accustomed to the study of political affairs, and who would therefore take a more particular view of what was revealed to him. Finally, we have the testimony of Christ himself as to the real and prophetic character

Willes.

# Danish Language and Literature

of the bock when he says, "When ye, therefore, shall see the abomination of desolation epokes of by Daviel the prophet, stand in the holy place, &c. [Matt. xxiv. 15].—Ref. Hongstenberg, Die Authentie, des Daviel; Horne's Introduction to the Old Testament; Jahn's

ditto.

Danish Language was originally a dislect of the so-called Old Norse, which, on account of the political superiority of the Danies over the other Scandinavians, was also called the "Done Norse the other Scandinavians, was also called the "Done Norse the other Scandinavians, was also called the "Done Norse the Old Norse; the Danish language. The Danish is the most changed of the languages derived from the Old Norse; the Swedish and Norwegian being less so, and the Icelandic least of all. The political union of the Danes with the Angio-Saxons under Cauute the Great, and the intercourse between the two nations that resulted thereform, had a considerable influence upon the Danish from, had a considerable influence upon the Danish language, to which the other branches of the Old Norsetongue were not subjected. Much more important and considerable was the influence exerted upon it at a later period from contact with the Germans. The Reformation introduces another era in the history of the Danish language; and the translation of the Bible into it gave it a fixed character, and raised it to the rank of a written tongue. As in Germany, so also in Denmark, a rage for everything French prevailed for a time, and many Gallie terms were then introduced. A reaction, however, took place in the latter half of the 18th century; and, since the beginning of the 19th, much has been done to restore and maintain the purity of the Danish tongue, by the establishing of a taste for Old Norse studies, and by the writings of such men as Baggesen, Ochlenschläger, Grundtvig, and others. Since the union of Norway with Denmark, towards the end of the 14th century, the Danish has been the literary language of Norway; and it is also the language of the educated classes, as well as that gene-rally spoken in the towns. The modern Danish is one of the softest languages now spoken in Europe. foreigner hears it spoken for the first time, he hardly perceives any sounds in it except the vocalic, the consonants being so much softened in pronunciation that they soarcely appear. The vocalic system is hence very perfect; and Dr. Rask has distinguished ten vowels, the sounds of which are all quite distinct. The inflections are few and simple, and the language is one that may be easily mastered. Although Denmark can scarcely be said to have possessed any national literature, properly so called, prior to the 18th century, yet its origin may be carried back to the time of the Reformation. The oldest remains of the Danish language do not ascend higher than the 12th century, and consist of laws of the early kings; as the "Skaanske Lov," the "Sjellandake Lov," &c. To the 12th century belong the works of the historians Saxo Grammaticus and the works of the historians Saxo Grammaticus and svend Asgesen, which, however, are in Latin. In the 13th century we meet with what seems to be the oldest of the Danish heroic songs, or Kjämpeviser, and which are still more numerous in the 14th (collected by Nyerup, Abrahamson, and Rabhek, 5 vols., Copenhagon, 1810-14; Supplement by Rasmussen and Nyerup, 2 vols., 1821). Like the German, the Danish owes fig character as a written language to the Referention. its character as a written language to the Reformation. The greatest writer of this period in Denmark, and in a certain sense the founder of modern Danish literaa certain sense the foundation (1480—1554), who, besides a rumber of other works, had a principal hand in the translation of the Bible. The literature which in the translation of the Bible. thus received a stimulus from the Reformation at first specially took a direction towards history, as well as to investigations connected with northern antiquities. There appeared in the 16th and 17th centuries not only a number of works of the first importance on the thistory of the country, both in Danish and Latin, but there were becau, even in the 16th century, investiga-tions into the northern antiquities which have been so successfully followed up in recent times by Haldersen. Olavsen, Magnussen, Rask, Rafor, Müller, Thomsen, Petersen, and others. The period of modern Danish poetry may be said to have commenced immediately after the Reformation. At first the subjects were generally of a sacred nature, as we see in the works of Rasch, E. Pontoppidan and others. Arreboe, who was the first of their epic posts, describes, in his great

## Darien Scheme

work, the "Hexameron," the events of the days of creation. Danial poetry resulted collmination during the time of the lyric post. Kings (1834—1723) and his contamporary Sorterup. A new epoch commenced with the and versatile Ludwig von Holberg, the create Danials tage. He, in the first half of the little and Ewald in the second, are considered to us golden age of Danials histerature. The first targety was Ewald's "Rolf Krage;" and best and Ewald in the second, are consurred to make any golden age of Danish literature. The first truly subtomal tragedy was Kwald's "Rolf Krage;" and beside him, as dramatista, stand Samsöe, Sander, and Thustup. Among the other poets belonging to this period, are Jone Buggesen, Tullin, Falster, Friman, Braun, Zetika, the brothers Trojel, Pram, and others. A new invitate was given to poetic literature by Ochlemenläger (1773–1851), who had as contemporaries in the same field, Stoffeldt, Ingemann, Grundtvig, Heiberg, Overskot, and others. Among the most recent poets as Heffs, Blicher, Hölst, Rosenhof, Winther, Von Hauch, F. L. Möller, and Molbech. As a poet and writer of there tales, Hans C. Andersen has acquired a European reputation. In the region of history are the names of P. E. Müller, N. M. Petersen, H. Engelstoft, J. Möller, Molbech, Werlauff, Knudsen, Bestrup, and Worsase; while important historical works have also been produced by G. L. Bader, F. L. Jahn, L. C. Köller, R. Allen, Nathanson, and Wegner. As publicista, are distinguished Direkinck-Holmfeldt and Catwald; as statisticians, A. Baggesen, Bergsoe, Nathanson, Baffander, P. L. Schaller, A. Baffander, distinguished Dirckinck-Holmfeldt and Ostwald; as statisticians, A. Baggesen, Bergsee, Nathansen, Buf, and Anschen. The services rendered by Schouw to physical geography, and by Oersted to physics and chemistry, are known and acknowledged for beyond the limits of their native country. Among theologians are Martensen, Myneter, Clausen, Nielsen, and Schamers and Martensen, Myneter, Clausen, Nielsen, and Schamers and among jurists, A. S. Oersted and Algreen-Ussing cocupys first place. As a philologist and critic, Madvig has made himself a European reputation; while Westergaard, from his knowledge of the languages of India and Persia, and Bröndsted and Petersen. from their knowledge of classical sationity. have guages of linus and rerais, and classical antiquity, have sen, from their knowledge of classical antiquity, have rendered good service to learning. The works of Thor-waldsen, presented by the artist to his countrymen, have created a taste for sculpture and the fine arts generally among them, and given a new direction to their mental culture.

DAPENE, dif'-ne (the Greek name of the laurel), in Bot., a gen. of plants belonging to the nat. ord. Thy-melaceæ. The species are mostly shrubby evergreens of great beauty, with leaves of a peculiar velvet tex-ture, and very fragrant flowers. The root-back of D. Mezereum, the mezereon, or spurge clive, is offi-cinal in the British pharmacopenas. It may be used as a vesicatory, and as a masticatory in toothache; but it is principally employed as a stimulant, diaphoratic, alterative, and diuretic. It owes its properties to an acrid resin and an acrid volatile oil. The stem bark The stem bark has similar virtues, but is generally considered to be less active. The fruit is acrid and poisonous; The bark of D. Laureola, the spurge laurel, is sometimes substituted for the officinal bark. The inner barks of D. cannabina and other species are used in some parts

of the world for making paper.

of the world for making paper.

DARIEN SCHEME, dair'e-e-n, an ill-fated under-taking, projected in 1695 by William Paterson, a clergyman in Scotland. This person having a strong desire to see foreign lands, made his profession the means of gratifying it. He went to the new Western world ostensibly to convert the Indians; but while there, he observed that on the Isthmus of Darien there was a treat of country which did not halong it there was a tract of country which did not belong to the Spaniards, and was inhabited by a race always at war with them. He also noted that the natural features of the country were admirably adapted to the construction of harbours and the formation of a colony. Paterson's original idea was to have submitted his project to England; but having few friends there, he was dis-couraged. He then applied to the Dutch, but they couraged. He then appear to the thirds, having made heard him with indifference; after which, having made the acquaintance of the marquis of Tweeddale, he re-solved that the scheme should be carried out in Septland. The Darien Company was consequently esta-blished by act of the Scottish parliament, and seme-tioned by royal authority. Its principal aim was go form a great commercial station between the Restern and Western hemispheres. When the subscription line

was opened, all classes superly subscribed, and in a very short time £400,000 were signed for in Scotland, although there was not ceall to the value of £800,000 in the singdom at that time. Afterwards England subscribed £300,000, and the Dutch and Hamburger £200,000. At this period, however, the jealousy of trade caused the English perliament to protest against the formation of the Basis India Company. The king interfered, and the result was the almost total withdrawal of the English and Dutch subscriptions. The Scotch, however, were not depressed by this opposition, but rather elasted; and on the £6th of July, 1896, twalve hundred men set sail for Darien from Leith five thiss. Nearly all the inhabitants of Edinburgh cause down to see them depart. On reaching their described in the entire. to the stage. Nearly all the inhabitants of Edinburgh come down to see them depart. On reaching their destination they purchased lands from the natives, and sent messages of amity to the neighbouring Spanish governors. The colony was called New Caledonis; the lite of the principal city, New Edinburgh, was fixed upon, and a fort commenced at Acta, called Fort St. Andrew. Everything succeeded for the first few months; but when the hot summer weather arrived, many of the colonists sickened and died. Their promany of the colonists sickened and died. Their proons began to fail them also; and on applying to the British colonies in America, they heard with indignation and dismay that the authorities, having learned that King William had not given his sanction to the scheme, After lingering eight months, waiting in vain for assistance from Scotland, they almost all died or quitted the settlement. About thirty of the colonists governer of Scotland. Paterson was one of these, and during part of the time in the passage home he was insane. or the time in the passage nome he was his inc. While these misortunes surrounded Paterson and his companions, the Scotch, ignorant of what had occurred, sent out another colony of 1,300 men to support the extinct settlement. A Spanish force of 1,500 men immediately attacked the new-comers, and after a gallant resistance they were finally obliged to quit the territory. Paterson never wholly gave up hopes that the scheme would be tried again; he survived many years, neglected, but pitted and respected. The Scottish India House in Edinburgh is the chief memorial of the Darien scheme, a project which very materially injured the commerce of Scotland, and excited a deeply hostile feeling against the English government and nation.

DAPER, dar'-ter (Plotus Ankinga, Liun.).—In general form this bird resembles the cormorant, but the head is smaller, and supported on a very long and slender needs. The beak is perfectly straight and pointed, with the edges of the mandibles denticulated. Buffon, in allusion to the darter, says, "It offers us a reptile grafted on the body of a bird." It is sometimes called the snake-bird. Its habits while in the water have contributed not a little to its name. It generally swims with its body immerged, especially when apprehensive of danger, its long neck extending above the surface, and vibrating in a peculiar manner. "Whether the darter be swimming or flying, it is certain that the most striking and remarkable part of its body is its long slender neck, which is continually in tremulous oscillation. In flight alone it is unmoved and stretched out, and forms, with the tail, a straight horizontal line.
Its long tail, composed of strong and elastic feathers, screen as a rudder when awimming submerged in pur-mit of flahes, upon which it principally feeds. When ant of false, upon when it principally leeds. when the darker esizes a small fish, it swallows it entire, but if it be too large, it carries it to a rock or the trunk of a tree, and, fixing it beneath one of its feet, cuts it in two by a stroke of its bill. It establishes its nest on treasor rocks in the vicinity of waters."—(Temminck.) The darker is found in the warmer parts of the world, in America, and Africa. Although of aquatic habits, it is said to build in trees

Distribute, dd-so-u-res (Gr. dasus, hairy; ouros, tail). This family includes the largest of the rapacious margingles. The largest of the species (Dasyurus ur-sines) measures about eighteen inches long in the body, and as covered with long thick hair; of a black colour, It is a matter of Van Diemen's Land, where it is com-monly known as "the devil." It is chiefly destructive monly known as "the devil." It is chiefly destructive which are widely distributed over the world. The only among sheep, and, despite its smell size, is capable of doing immesses satisfair among the penued flocks, which is employed in Cashmers for dyeing yellow.

When Van Diemen's Land was first colonized, "devils" were very abundant; but they are now for the most part bamahed to the woods in the unfrequented parts of the country, where they missist on small quadrupeds and birds. The feet of the dayyarus are formed for terrestrial progression; the anterior have five toes, and the hind ones four, all perfectly separate, and armed with curved claws. The deficient toe of the hind feet is cometimes represented by a cort of tubercle, which, however, does not reach the ground. The teeth are usually forty-six in number; the form of the molars in the upper jaw is usually irregularly triangular, with three points. The dayures are evidently snalogous to the ordinary carnivorous guadrupeds, not only in their ferocity and carnivorous proposities, but also more or less in form.

DATA, dai'-td (Lat., things given), in Geom., are certain things or quantities which are given or determined by the conditions of a particular problem. A thing is said in general to be given which is either actually exhibited or can be found out; that is, which is either known by hypothesis or can be demonstrated to be known. be known. Hence, in the analysis or investigation of a problem from the things that are laid down to be known or given, by the help of known propositions, other things are demonstrated to be given; and from these, other things are again shown to be given; and so on, until that which was proposed to be found out in the problem is demonstrated to be given. In the book of Data ascribed to Euclid, which is the most valuable of the works left us on geometrical analysis by the Greeks. the word is used for such spaces, lines, and angles as are given in magnitude.—In Philosophy, Medicine, &c., the facts from which an inference is drawn are called data.

DATE, dail (Lat. datum, given), the time when an event happened, or when anything is to be done. The date of an event, or of a document, is often of great importance; but it is frequently a matter of great difficulty to ascertain it correctly. One of the chief obstacles is the difference between the two styles by which dates are reckoned, and through which a discrepancy of between ten and twelve days may be made in the calculation, according to the century to which the date belongs. There was only one style of reckening the date belongs. There was only one seyrou avanua-time in Europe until 1882, when Pope Gregory XIII. introduced the "new style," which declared the 5th of October, 1582, to be the 15th, thereby correcting a number of errors which had accumulated. The ten number of errors which had accumulated. The ten days were then struck out, and nearly all Roman Catholic countries adopted the new style; the Protestant countries, however, retained the old or Julian calendar, for a longer or shorter period of time. (See CALENDAR.) Thus, in all dates after 1582, it is necessary to accertain whether the old or new style was used at the time and place specified. Many old documents are dated from some particular service of the church on the day of writing; and in some nations, for a great length of time, it was customery to date from the year of the monarch's reign.

DATE OF A DEED, is the description of the time, viz. the day, month, year of our Lord, year of the reign in which the date was made.—1 Inst. 6. (See DEED.)

Which the date was made. I me. to (NE)
DATE-PALM and DATES. (See PHENIX.)
DATHOLITE, dath'-o-life, in Min., a boro-silicate of lime, found in various parts of the world in oblique. rhombic prisms. It also occurs in botryoidal forms, when it receives the name of botryoids. It is found rather abundantly near Lake Superior, where it is profitably employed in the manufacture of boracic soid.

It is also used as a flux for copper ores.

DATISCACEE, dui-tis-kui-se-s (deriv. unknown), in Rot, the Datisca fam., a nat. ord. of dicetyledonous plants in the sub-class Monochlamydem, consisting of herbs and trees having the following botamical characteristics. neros and trees having the following botanical charac-ters:—leaves alternate, excipulate; flowers diclinous; male flower with a 2—4-cleft calyx; 3—7-framens; anthere 2-celled, linear, bursting longitudinally; female flower with a superior 3—4-toothed calyx and a 1-celled ovary, with 3—4 polyapermous parietal piacentas. Fruit dry, opening at the apex. Seeds without abumen, minute, numerous. The whole order includes but four apsecies, which are widely distributed over the world. This only

Dawn, duen (bax daquen), the break of day, the
twilight, or half light that occurs between the first

appearance of light and the rang of the sun.

DAY du () at deg, probably from Int. deep,
that period of the earth's revolution on the suns in
al all its surface is presented to the sun. The term is, however, applied to any astronomical space of time which depends directly on the earth's rotation. But which depends directly on the care a rorange. Due the only days desinguished by that name in astronomy are the sidereal day, the real solar day, and the mean soin day. The sidereal day is the period heaven the two transals of the same fixed star, that is, a complete revolution of the cith. It is divided into twenty-four revilution of the cith. It is divided into twenty-four hours and begins when the equinox is on the meridian of the place. The real solar day is the interval between two transits of the sun over the meridian. The length of the real solar day values at different periods of the year, on account of the unequal motion of the sun and the obliquity of the ecliptic. The mean solar day is the average of all the real solar days. The mean solar time is thus arrived at by imagining a sun moving uniformly in the celestial equator and completing its circuit in the same time as the real sun. The real and mean solar days only coincide in four the real and mean solar days only coincide in four days of the year. In the intervals the sun is either too fast or too slow The difference is called the Equation of Inne (which see). The mean solar day is 34 hours minutes 56 55 seconds of sidereal time; and the i minutes 56 5 seconds of midereal time; and the sudcreal day is 28 hours 56 minutes 40g seconds of a mean solar day. The ancients generally began their day at sunrise, with the exception of the Egyptians, who began at midnight, and the Arabhans, who began at moon. The latter nation still retains the same custom, and most of the modern Eastern national reckon the commencement of the day from sunrise. A day is Loss uncludes the whole twenty-four hours, without reference to light or darkness. Unless there illet, the Weish still wear the leek on it David's day DAWY-LAWS, day't to kimp, in Miu, a lamp invented by Sir Humphry Davy to obviate the leavid explosions liable to take place in coal-mines from taking ranked lights into places containing firedamp, a light rection the commencement of the day from sunrise, that when a lamp is surrounded by wire gauze, the meshes of which are under the fortich of an inch, and provides the whole twenty-four hidner, that when a lamp is surrounded by wire gauze, the meshes of which are under the fortich of an inch, and provides the whole twenty-four hidner, that when a lamp is surrounded by wire gauze, the meshes of which are under the fortich of an inch, and most of the modein Eastern nations, that when a lamp is surrounded by wire gauze, the meshes of which are under the fortich of an inch, and the commencement of the day from sunrise.

Adv at sunrise, with the exception of the Egyptians, who began at midnight, and the Arabanas, who began the countries.

(See EPHEMERA )

www.Gr. ductoros, a servant or minister), a New Testament for any one that ministers so of God, and it is also sometimes used by ecclenistical writers, when it includes of presbyters as well as deacons, but it is now by simpleyed to designate the third or lowest of the angles in the Christian priesthood. The prirue tares orders in the Unishan priesthood. The primitive deacons took care of the secular affairs of the Church, received and disbursed moneys, kept the abuuml's seconts, and provided everything necessary for its temporal good. We have an account of their first implification in the sixth chapter of the Arts of the Apostor; and in the third chapter of the First Epistle
to Timothy we have the qualifications specified that
were appearant to the office of a deacon. There were were necessary to the office of a deacon. There were also descenesses in the primitive church, one of whom was Phoshe (Rom. xvi. 1), and this order, though generally dispased in the Western church in the 5th century, continued in the Eastern until the 12th In the primitive church, the deacons were styled "ministers of the mysteries of Christ." It formed part of their duties to take care of the holy table, and the ornamenta and utensis appertanting thereto, and to receive the oblations of the people and present them to the priest. In some churches they read the gospel in the communion-service, and ministered the bread and wine to the people in the Eucharist they also baptized, and, with the bishop's license, sometimes preached. They with the bishop's license, sometimes preached. They were also went to direct the people in public worship, many existant known forms of words it give notice when each part of the service began, and they cometimes represented the bishop in general council. The Charch of England enjoins that "none shall be admitted a deacon, except he be twenty-three years of each indicate whe land down as follows—"It appertained to the office of a deacon, in the church where he shall be appointed to serve, to assist the priest in divine service, and specially when he ministered the holy commission, and to help him in the distribution thereof, and to read Enjy Scripture and homilies in the church and to read Holy Scripture and hondies in the church and to instruct the youth in the catechism, in the observe, of the priest to baptize infants, and to preach, if he is admitted thereto by the bishop. And, further more, it is his office, where provision is so make, to search for the sick, poor, and impotent people of the patish, to instinute their estates, names, and places where they dwell, unto the curates, that, by his experience, they may be relieved with the alms of the patishioners or others." In the present day, the more combined duties of the officer hand day, the more combined duties of the officer hand day, the more and to read Holy Scripture and honulies in the church soulise duties of this officer have devolved the fly upon churchwardens and overseers of the poor, and his spraining functions have been more extended. He may ociebrate matrimony and the burial of the dead, in fact, perform all the ordinary offices of the istian priesthood, except consecrating the elements

or iron bands, which, with the bein of other tackle, from a purchase for orbinding the abrouds and stays, otherwise called the standing rigging.

Dian Lawauaus is a beam amployed to denote such languages as are now no longer spoken by any people or nation, in contradistingtion to assis as are so spoken, and are known as bring languages.

Dran Reckoring, the mane given in Mar. to the method of determining the position of a ship at sen by a calculation based on the following data; the latitude and longuide from which the vessel saited, which is a calculation based on the following data; the latitude and longitude from which the vessel sailed, which is generally called its point of departure; the time which has elapsed since it left this point, or any other of which the latitude and longitude have been properly determined, the direction in which the wessel is sailing, as an an an analysis of the compass; and, lastly, the rate of sailing, as crumed from measurement by the log. (See Loc.) In this method of calculation, no regiouse is had to observations of the sun, moon, sid signs; but, owing to changes of the wind, the influence of currents, and a variety of causes which affect the currents, and a variety of causes which affect the course of the vessel, the results of the computation cannot be depended on, and they must be corrected by calculations made from observations of the heavenly bodies

DEADLY NIGHTSHADE, or DWALE. (See ATROPA.)

DEAF AND DUME, def dum (Sax. deaf dume).—A

person is said to be deaf when he is other entirely or person is said to be deal when he is under entirely or a great measure destitute of the sense of instring, and dumb when he is without the power of speech or of articulating sounds. Such individuals are also sometimes called deal-mutes. Deafness is either congenital or acquired. When congenital, it arises from an experimental of the article statement of the article sta or acquired. When congenital, it arises from an original maiformation of the ear, and is always accompanied with dumbness, when acquired, it is the result of some disease affecting some of the delicate parts connected with the origan of hearing (See Draffers, Dia, Hearing). The ear is necessary to articulation, which is acquired by initiating the sounds we hear uttered by others, and therefore it a management. uttered by others, and, therefore, if a person is unable to distinguish between articulate sounds, had unable to distinguish between arriculate sounds, he is incapable of acquiring speech, at least in the ordinary way, and is dumb in consequence of his desiress. It is tare indeed to find dumbnes in deaf persons resulting from any imperfection in the organs of speech, or from feebleness of mind; and hence the fallacy that till recently prevailed, that the want of the power of speech was owing to a mental or physical incapacity of the individual, who was thus incapable of receiving education. Persons who have lost puble of receiving education. Persons who have lost their hearing after having acquired the use of speech, and who are thus still able to communicate their ideas. orally to others, do not come under the class of deal and dumb This affliction is much more common than, for a long time, and up to a very recent pariod, it was believed to be The census of 1951 was the first that believed to be. The census of 1951 was the first that revealed to us the number and proportion of designal dumb in this country. According to that return, we find the number of deaf mutes in the United Kingdom to have been at that time 17,300, or one to every 1,550 of the entire population. The relative proportions, however, differ much in different parts; being, in Herefordshire, as high as one in 1,05; in Wordestershire, one in 1,100, and in the northern countries of Scotland, one in 1,156. In the ex-metropolitan portion of Kentingsun there is only one in every 2,349; in Durhard, one in 2,150, and in Huntingdonahire, one in 5,016. What the causes are which produce dealness are say without very imprefectly known or understood. There can be very imperfectly known or understood. There can be The issue preschood, except consecrating the chemits in the Eucharist and pronouncing the sholution. He supported in the Eucharist and pronouncing the sholution. body, and which is, in fact, essential to its diseased well-being; and systemic or smooths, which is the death of the body as a whole. Bomakis death may result either from the general failure of the vital powers, as either from the general failure of the vital powers, as in old age, or from some flagues, or injury in some of the vital organs, which extends itself to the organism in general. It may be due to failure in the propulsive power of the beart, which constitutes symope; and this may occur either in consequence of the heart losing its irritability, and so couning to contract, or by being affected by tanit spasm, and so remaining rigidly contracted. In both cases death is instantaneous; the subject turns suddenly pale, and falls back, or drops down, exprising with one gasp. Or death may take place by the gradual cessation of the action of the heart; in which case it is termed asthenia. Somatic death may also be occasioned by an obstruction to the death may also be occasioned by an obstruction to the flow of blood through the capillaries of the lungs, or to the entrance of air to these organs, thus constituting applying, or appear. Death by come, or beginning at the brain, is caused by various influences, which primarily destroy the functions of the superior masses of the nervous system. The chief of these are obstruction to the circulation of the blood through the brain by pressure, and the effects of certain narcotic poisons, as opium, &c. As the ordinary act of breathing depends upon the nervous action of the medulla oblongata and inalis, it is quite evident why death may result from an impaired state of these organs; and this mode of leath is of the nature of approa. Death may also be death is of the nature of apprea. occasioned by a disordered condition of the blood itself, which at the same time weakens the power of the heart, impairs the activity of the nervous system, and prevents the performance of those changes in the capillaries which afford a powerful auxiliary to the circulation; this is termed death by necramia, and circulation; this is termed death by necromia, and occurs in typhoid fevers, and other diseases of a malignant or pestiential kind. Death may also result from the direct agency of cold stagnating all the vital operations of the system. It is to be borne in mind, that death is featured as that death is frequently produced by a conjunction, or by the rapidly-following results, of two or more of these modes; indeed, the perfect distinction of these different modes of death is almost exclusively confined to cases where the dissolution is speedy or sudden. The signs of approaching death are necessarily various The signs of approaching death are necessarily various, and depend, in a great measure, upon the nature of the disease. We shall notice some of those that are common to most diseases and to natural decay. In some cases there is a dulness of the senses, inactivity of the sauscles, vacancy of the intellect, and extinction of the sautiments, as in death resulting from old age. There is, also, frequently some degree of delirum, which is often of a most interesting and pleasing characteristic and described of a most interesting and pleasing characteristics. ractor, recembling dreaming more than any other form of derangement; sometimes, again, the dying fancies of the individual are of the most dreadfully distressing character; but it is presumptuous, as many do, to hazard much upon the various modes of terminating the arrest of life. In the delirium the reproduction of ensations often bears a considerable part ; and frequently the victim of typhus is seen catching at something in the air, or picking at it on the bedelothes. The sense of hearing is frequently also affected, and imaginary voices, and sounds of tolling bells, &c., are maginary vales, and sounds of tolling bells, &c., are heard: Dementia, or mental debility, sometimes comes or shortly before death, and for the most part manifests itself in an incapacity of concentrating the ideas upon say one object, and by an all but total failure of the memory; this mental weakness often painfully manifests itself in the apparent pleasure which the sufforer takes in some of the most childish amusements. The trying memorally becomes low and weak as death The rener generally becomes low and weak as death approaches; but sometimes it has a shriller pitch than natural cometimes it is husky and thick; and not unfrequently it dwindles to a mere whisper. The musstequency in wanter to a mere wisper. In income seems system generally becomes feeble and relaxed; the pulsations of the heart gradually feebler, but more frequent; the respiration sometimes hurried and passons, nometimes easing gradually; and sometimes slow, laborious, and stertureous. There is frequently, and stertureous there is frequently or the sterile of finite removed services. also, an economication of finide,—mucous, serous, or angel of death, called Samasi and frince of the Weste, purelent, in the bronchial tubes. What is known as the "death-entile" is produced by the passage of the king through the fluid collected in the representation of death (a skeleton with a serties)

620

tracken and upper respiratory passages. The maribund are often impatient of any kind of clothing, throwing off the bed-clothes, and lying with thest bere, the arms off the best-clothes, and lying with thest base, the arms extended, and the sack as much expressed as possible. Among the other signs of approaching disselution, are the nuken eye, the hollow temple, the sharpened nose, the forebead dry, tense, and harsh, the complexion shallow, livid, or black, the lips cold, flacoid, and pale, or of a leaden hue. We believe that the opinion that generally prevails of the great amount of suffering that immediately precedes death, and which is expressed by such words as the death-struggle or agony of death, is very erroneous. There is every treason to believe that as death approaches, the scustbilities are gradually deadened, and that in most cases consciousness has ceased before the struggle commences. The number of suspenses of successions, when the show assuing, or surging muscular spasms, — the slow, gasping, or surging breathing,—the collapsed or distorted features, though in some cases accompanied by feeling, are altogether in some cases accompanied by feeling, are autogener, independent of it. Convulsion is not, as superficial theservers often imagine, a sign of pain; it is an affection of the motifie, not of the senside part of the nervous system. Those who have made the nearest approaches to actual death, as in drowning, have described their, feelings as being of an extremely pleasurable kind; and a late eminent physician told his attendant friends on his deathbed, that "he wished he could be at the trouble to tell them how pleasurable that a thing it was taddled." trouble to tell them how pleasant a thing it was to die. We believe that dving is not less truly than beautifully described in Scripture as being a "falling saleep;" idea which was also entertained by the ancient Gree who regarded death as the twin brother of sleep. The consequences of death first become apparent in the organs of sense and motion; the eve less its brightness, and the flesh its elasticity; the muscles become stiff, and coldness and paleness spread over the whole body. Yet it is often a very difficult matter to distinguish between real and apparent death. The most reliable test is afforded by the condition of the muscular substance; for after real death this gra-dually loses its irritability, so that it can be no longer excited to contraction by any kind of stimulation; and this loss of irritability is succeeded by the appearance of cadaveric rigidity. The most satisfactory proof.

this loss of irritability is succeeded by the appearance of cadaveric rigidity. The most satisfactory proof, however, is given by the occurrence of putrefaction, which usually first manifests itself in the blue-green coloration of the cutameous surface, especially of the abdomen, but which speedily extends to other parts,—Ref. Todd's Cyclopadia of Anatomy and Physiology. Carpenter's Human Thysiology, Miller's Physiology. Dearu, in Myth.—It is not to be wondered at that an eyent so impressive and so deeply interesting to all should have excited the attention of every people, and led them to form very different ideas regarding it. It is indeed remuskable that the Greeks, whose conceptions of an after-life were so gloomy, should have represented death as a pleasing, gentle being; while the Christians, whom religion teaches to look upon death as a release from bondage,—a change from misery to happiness, give him a most frightful said disgusting shape. According to the theogony of Jesied, mesery to happiness, give him a most frightful and disgusting shape. According to the theogony of Hesisal, the god of death was the offspring of Night and the twin brother of Sleep. During the most flourishing period of the arts in Greece, Death was represented on tombs as a friendly genius with an inverted torch, and holding a wreath in his hand; or as a sleeping child, winged, with an inverted torch resting on his street. Step was represented in the same was street. Sleep was represented in the same mann except that the torch and wreath were omitted. According to an idea originating in the East, death in cording to an idea originating in the East, death in the bloom of youth was attributed to the attributes of some particular deity, who snatched his lavourite to a better world. It was ascribed, for real-soes to Jupiter, if occasioned by lightning; to the Nymphs, if by drowning; to Aurora, if happening in the accurage, &c. The representations of death by the Bonisms were less pleasing than those by the Orient; and among their later poets we find death represented under some horible forms, gnashing his teath and marking his victims with bloody nails, a monator extended owing whole fields of buttle. The Habrews had also a tearful angel of death, called Samail and Princet the Wurld.

# Death, Civil

common among Christians, originated in the 14th cen

common among Christians, originated in the 14th dentury. In recent times, however, the success sides of death as a beautiful youth has been revived.

DEATH, CTVIL. (See CTVIL DEATH.)

DEATH, in Theol., is used in a much wider sense than it is no ordinary language, as is also the word life, to which it is opposed. In theological language, there are three kinds of death,—temporal, sprittinl, and eternal, as there are three kinds of life, to which each of these is respectively opposed. The first of these is temporal death, or the death of the body; the second is suiritual death, or the next condition of the soul temporal death, or the death of the pony; the second is spiritual death, or the natural condition of the soul under the power of sin; and the third, or eternal death, denotes the everlasting perdition of the wicked. As Adam introduced death into this world, so Christ, by his sufferings and death, has brought life. He has taken away the sting and power of temporal death, has brought and provided to all the propried to all t has introduced spiritual life, and has promised to all that believe and follow him life everlasting.

DEATH'S-HEAD HAWE MOTH (Acherontia atropos), a lepidopterous insect of the family Sphingide. It is a species of hawk-moth found in several places in England and in nearly every quarter of the globe. Its langth across the wings is nearly five inches; its body is of a yellowish colour, with black stripes; the markings woon the back of the thorax are faint, but hear a close resemblance to a skull or death's head, from which it derives its name. The wings are dark-coloured, being mottled with yellow, brown, and black. The ceterpillar of the death's head moth is greenishyellow; the back is covered with black specks, with transverse lines of blue and white. It is often found feeding upon the leaves of potatoes. The moth itself is mostly seen flying during the morning and evening in autumn. As it flies, it utters a low, plaintive sound, and this, together with the death's head mark upon the thorax, have caused it to be generally regarded with distavour. How it contrives to make the noise is not known. Another strange property possessed by the death's-head hawk-moth, is that it is able to enter and plunder bechives with perfect impunity.

DEATH-BED, LAW OF, IN SCOTLAND.—A man who has burdened or conveyed away his hereditable estate, to the prejudice of his lawful heir, while suffering from disease of which he oventually dies, is held to have seted thus in consequence of inability to resist importunity in his then enfeebled state. His beir may therefore reduce the deed. It is probably referable to the same principle as the prohibition to convey heritage by will, as being designed to protect the dying and their lawful heirs from the rapacity of the priesthood. The legal tests of the amount of vigour are, survivance for sixty days, or unassisted attend-ance at " kirk" or market, though only accomplished for the evadence of the law itself. Death by accident

would, however, validate the will of an already mori-bund man.—Ref. Chumbers's Encyclopedia.

DEATH-WATCH (Anobium tesselatum).—There are certain superstitions that, once rooted in the light soil of a small mind, can never be eradicated or grubbed out by the keenest weapons common sense can bring to bear against them. The insect under consideration is a case in point; and there can be little doubt that this tiny beetle has caused more quaking and consternation than ever did Tigris regalis, or the king of beasts itself. Authors were formerly but ill-agreed as to the insect emitting the delorous ticking. Some attributed it to a spider, others to a wood-louse. It is, however, now generally received as authentic that the "death-watch" is produced by certain beetles the "death-watch" is produced by certain beetles belonging to the timber-boring genus Anobium. The insect in question is of a greyish-brown colour, about a quarter of an inch in length, and moderately thick in proportion: the wing-shells are marked with irregvariegations lighter than the ground-colour. The ticking noise is thus produced :- raising itself upon its head with great force and against a sum of the head with great force and against a sum of the woodwork on which it is standing. The general number of distinct strokes in ancession is from seven to eleven. They follow each other quickly, and are repeated at uncertain intervals. It is said that this insect, if caught and confined on a table, may be taught to knock in reply to a tap of the finger-nail. This training, however, must be a work of some little time, for it is well known

## Debility

that the death-watch, as soon as touched, will contract its legs and counterfeit death, maintaining the imposition even when subjected to a heat flerge enough almost to reast them. The ticking is messely the call of either serie its mate, and may be considered analogous to the call of birds. Says Sir Thomas Brown in his learned. "Facundoxia Epidemica," "He that eguld cradicate this error from the minds of the people would save from many a celd sweat the meticuleus heads of nurses and grandmothers."

DEBATS, de-bait" (Fr. dbat), is a formal swchange of opinious between two or more persons, with the

of opinious between two or more persons, with the view of arriving at some definite conclusion. The The subject is usually treated in a definite manner, and the speakers succeed each other according to certain rules. There is frequently a chairman or president, whose business it is to see that order is maintained. and that the debate is properly conducted. Debate is, even in a greater degree than conversation (whicheet), calculated, if properly conducted, to improve the mental powers. It does so in so far as the heat and vehemence of debate are calculated to excite the faculties to greater statistics than its results. ties to greater activity than is usually the case in conversation. The effort to be sustained is also conversation. greater; the ideas have to be arranged systematically, the words well chosen, and the various forms of exposition, persuasion, and appeal have to be resorted to in order to gain our object. Many roung persons imagine, that in order to train themselves to the art of public speaking, it is useful to adopt that side of the question under debate which to themselves appears the weakest, and thus to display their ingentity in trying to make the best of it. There cannot be a trying to make the best of it. greater mistake. All high eloquence is the offspring of passion or warm emotion; and a man, to be sloquent, must be in carnest, and feel that he is uttering his own sentiments. They will improve themselves to more advantage, and acquit themselves with more honour by choosing always that side of the debate to which, in their own judgment, they are most inclined, and supporting it by what appears to themselves most solid and persuasive. They will acquire the habit of reasoning more closely, and expressing themselves with greater warmth and force, when they are adhering to their own sentiments than when they are speaking in contradiction to them. Neither should one venture to speak upon a subject which he has not studied beforehand; for, in order to speak well, a man must feethat he has his mind made up upon it. A too early adoption of the practice of debate is, however, apt to lead to very reprehensible and often incurable faults, inducing young men of immature judgment and superficial knowledge to advance and adhere to opinions which can only be supported by sophistry, and to con-tend for victory rather than for truth. In this way a habit may be formed, which will not easily be unlearned afterwards, of disregarding right reason and truth, and fair argument. The practice of debate should be preceded not only by general cultivation of the mind. but also by much practice in writing. At first, at least, the substance of what is to be spoken on each occasion should, after reflection, be written down, not in the words designed to be uttered, but in brief heads, so that as little as possible may be left for the speaker to

Trane at the moment, except the expressions.

Defending the deben the expressions.

Defending the expertence of conton-house certificate, authorizing the experter of certain classes of goods to receive the amount of drawback to which he is entitled upon the goods. It is also applied to a deed by which a railway company mort-gages its property for the payment of a certain sum of borrowed money, at the time and under the conditions specified. A debenture is also an instrument by which the government is charged to pay to a creditor or his assigns the money found due on auditing his

DEBILITY, de-bil-e-te (Lat. debilitae, weakness or decay of strength), in Med., is defined to be "that departure from the healthy condition of the frame which consists of a diminution of its vital enerwhich consists of a diminution of its vina ther-gies,—of an enterbing of its powers, manifested in numerous conditions and grades throughout the whole frame, or more or less remarkably in particular sys-tems or organs." It is intimately connected with the nature of most diseases, and often constitutes disease

of itself. Numerous attempts have been made to distinguish or classify the different kinds of debility. The most recent writers regard it—(1) As direct or premary, arising from the abstraction of stimuli, or the operation of contra-stimuli, or such substances as directly onfeetle the organization; (2) judirect, consecutive, or secondary, arising either from exhaustion occasioned by previous excitement, or from increased excitation of an organ occasioning proportionate diminution of the energy of others; and (3) compliexcisions of an organ occasioning proportionate diminution of the energy of others; and (3) complicated debits; consisting nof only of depressed, but of otherwise morbid or viriated vital action. Besides the conditions that characterize general debitity, there are also specifie or partial states of debitity, manifesting themselves more particularly in certain of the tissues, Organs, or systems; as the circulating or nervous system; the organs of digestion or secretion, the cellular tissue, &c. The treatment of debility will always, in a great measure, depend upon its particular form and cause; and these are necessarily so many and varied, that no special directions can be laid down regarding There is, however, a particular class of remedies It. There is, nowever, a particular than the called tonice, which are in general more beneficial than any other, although other articles, as diffusive stimulants and antispasmodics, may often be used with great advantage. Tonics have derived their name from their manufacture that the tone of contractile marks. influence in angmenting the tone of contractile parts, elevating, in a gradual manner, depressed vital power almost up to and seldom or never above the healthy standard. They are also characterized by the perma-nency of their action. Change of air, moderate exercise, agreeable occupation, and pleasant society, are also among the most beneficial means of restoring the depressed or exhausted powers of the frame. Sea-bathing, and in some cases medicated baths, are likewise often of great benefit.—Ref. Copland's Dic-

tionary of Medicine.

DEBIT, deb-il (Lat. debeo, I owe), money due for goods sold on credit or for services rendered. It is generally written debt; but in mercantile language the word is mostly applied to the debit side of an account, which is generally entered on the lett-hand page of the ledger. The term is also applied to the entering of an account on the debtor side of a book; as, to debit the

sum or amount of goods sold.

DEBOUCETING, de-loosh'-ing (Fr. diboucher, from de, from, and bouche, the naouth).—In Min, troops are said to debouch when they emerge from any wood or narrow pass into a plain or open country. The application of the term is obvious from the derivation.

Dinners, dat-bree' (Fr.), a French term which has been generally adopted by geologists, and applied to masses of broken rocks, &c. In ordinary conversation,

the fragments of any fallen building, such as a house

the ingrments of any latter building, such as a house or bridge, are called the debris.

Direct det (Lat. debee, I owe), is that which one person owes to another, whether it be money, goods, or services. In Law, debts are usually divided into debts of record; debts by special contract, and debts by simple contract. A debt of record is a sum of money which appears to be due by the evidence of a court of record, or adjudged to be due on an action at law. A debt by specialty, or special contract, is where a sum of money becomes due, or is acknowledged to be due, by deed or instrument under seal; such as by deed of covenant or sale, by bond or obligation, &c. A debt by simple contract is an obligation depending upon mere oral evidence, or upon notes unscaled; within which class fall bills of exchange and promissory notes. Debt is also a personal action of contract which lies for the recovery of a debt in its technical sense, i.e. a certain amount of money due by one person to arother.

DEBT, NATIONAL. (See NATIONAL DEBT.) DEBTOS AND CREDITOR, det-or, kred-it-or.—The former is one who owes a debt to another, the latter is the person to whom a debt is due. In the early history of every country it will be found that the laws against debters are much more severe than at a later period of its civilization. In rade states of society the creditor was not only entitled to seize the goods of the debtor in satisfaction of the debt, but frequently also he had the power of ensisting the person of the debtor and all who were dependent upon him. We find evidence of this in the early laws of Greece and Rome. The

right of a areditor to sell his debtor was abolished at Athens by Solon. At Rome the debtor was subject to be taken by the creditor to his own house, and there treated in the most cruel manner for sixty days; and if at the end of that time no one stepped forward to release him, he might be sold for a slave. This power of the creditor over his debtor seems to have become practically obsolete, and a milder mode of treatment to have crept in under the emperors. According to the Institutes of Justiniau, a debtor was subject only to les institutes of Justimun, a debtor was subject only to loss of property for payment of his debts. Among the Jews, while the law of Moses admitted of the person of a debtor being sold into bondage, it also provided for his merciful treatment, and enacted a certain time for his being set free. The poor Hebrew was not to be compelled to serve as a bond servant but as a hired servant and as a sojourner, and was to be set free on the year of jubilee, he and his children; and he was to return unto the possession of his fathers. During the feudal period the person of the debtor could not generally be seized for debt, such a proceeding being inconsistent with the duties of military service, to which every man was bound. This was also the case in England at an early period; suits were commenced by a summons, and if the defendant failed to appear, process was issued for the attachment of his property; but in actions upon contract no further remedy was given, either at the commencement of the suit or after judgment. In actions for injuries accompanied with force, it was, however, permitted to issue process for the arrest of the person. By various subsequent statutes the same remedy was catended to other actions in which there was no force; as actions of account, debt, detenue, and actions on the cause. In the court of King's Bench, however, the defendant was, without the mid of these statutes, liable to arrest upon process issued for an alleged trespass, and when arrested he was made to answer for any other cause of action. In the court of Exchequer jurisdiction was obtained by a similar fiction: upon recovery of judgment in any action in which an arrest was allowed upon mesne process, a writ could be issued, called capital estisficiendum, whereby the defendant could be arrested and committed to close custody. Important modifications have recently been made in the laws of debter and creditor.—Sice Banketprex, INSOUTENT,

Indusonment, &c.
Dieut, dai-ba', a French term which has been adopted as an English word. It properly means an opening or beginning, but it is more especially applied to the first appearance in public of an actor or actress. It is also applied to the first appearance at any particular theatre of an actor or actress. In either case the actor is called a débutant, and the actress a débutante.

DECADENCE, de-kai'-dens (Lat. de, from; cadere, to fall), a term applied in the Fine Arts to the decline of any school of painting, or the literature or architecture of any country, from the point at which it may be considered to have reached its summit of perfection. In the Bolognese school of painting (see Bolognese School of Painting (see Bolognese School of Painting), for example, the works of the artists belonging to it reached the highest degree of excellence in the productions of the Carnot, although the Caracci themselves are said to belong to the decadence of the more comprehensive Renaissance school. which culminated in the paintings of Raffaclie, England, architecture, especially church architecture, las been in decadence since the Tudor period, and perhaps, more strictly speaking, from the 14th century, when Gothic architecture attained the highest degree of excellence in this country. But the period of its decadence is now past, and it is beginning to revive again, as well as other branches of art, by the substitution of Byzantine and Gothic forms for the hideous imitations of classic architecture that disfigure the ecclesiastical structures of the 17th and 18th centuries. In Rome, literature attained its highest point in the prose writings of Cicero and the poetry of Horace, Virgil, and Ovid, and the works of other Latin authors of the Augustan era; but when these men had passed away, the decadence commended, and later works in this language are not marked by the elegance and purity of diction which characterized the writings of those who have been mentioned.

## Decagon

Decagon, dele'-d-gire (for, delet, ten; gonta, angle), a geometrical figure which has ten sides and ten angles. When the sides and angles are all equal, the figure is called a regular decagon, and is insuripable in a circle. An irregular decagon, can be founed from a pentagon by describing any irregular tenangles upon its sides, so that no two of them shall have their aideain the same straight line.

DECALOGUE, descalor (Gr. desa, ten, and logos, word), is literally the ten words, a sense which the Hebrewas well as the Greek term bears, and is applied to the law of the ten commandments as given by God to Mouse on Mount Signi. These were written on two tables of stone by the inger of God himself, and were thus different from the other precepts of the law, which were given through Moses; while their being written on "durable tables of stone" serves to denote their ever-binding nature. The Decalegie, like many other por-tions of Scripture, has afforded subject for minute criticism for those that are ever on the search for hidden meanings. Thus, they tell us that the number ten is the symbol of completeness, indicating that they form by themselves an entire whole, made up of the necesry, and no more than the necessary, component parts; that they were written on both sides so as to cover the entire surface, and not leave room for future additions. Much dispute has arisen as to how the commandments were divided on the two tables. It is generally admitted that the first comprehended our duty to God, and the second our duty to man. According to Josephus, however, there were five commandments upon each table, and two and a half upon each side; and Philo-Judieus adopts the same view. The more general view among Christians is, that the first table contained only the first four commandments, and the second the remaining six. But the Roman Catholics, who threw the two first commandments into one, and split the last into swood. The difficulty lies with the fifth commandment ("Honour thy father and mather," &c.), whether it is to be regarded as coming under the head of love to God, or to our neighbour: Christians have generally regarded it as belonging to the latter. Scripture, however, always looks upon parents in a very peculiar light, and very different from what is implied in the general term hiour. It rather regards them as representatives of God, to whom he has delegated a portion of his authority, and for whom he consequently exacts a porunscriptural in the view which places honour to parents due unto himself; and filial obedience as a part of Christian worship. The more closely the commandments of the Decalegue are examined, the more clearly do we perceive their spiritual and comprehensive character, and their suitability for all time. They recognize love They recognize love as the root of all obedience, and hatred as the root of all transgression; and the love that is required is no shallow and superficial thing, finding its development in a few easy external acts, but, on the contrary, it embraces the entire field of man's spiritual agency, and has respect alike to his thoughts, words, and deeds. They comprise a brief but comprehensive summary of all religious and moral duty. In the first table of the law the first and second commandments point to the now the first and second commandents point to the role Godbead, and absolute spirituality of God, requir-ing for himself personally, and for his worship, that place in the heart to which they are entitled; the third demands the due honouring of him in word; and the fourth and lifth the honouring of him in deed. In the second table we are commanded not to injure our neigh-

second table we are commanded not to injure our neighbour,—1, in deed, that is (1), in his person (6th commandment); (2), in his family (7th com.); or (3) in his property (5th com.). 2. In word (9th com.); or in thought (through covetousness, 10th com.).—Ref. Typiographs of Scripture, by Dr. Fairbairn, 1837.

DROINERON, delc-am'e-ron (6r. delca, ten; emera, day), the name given by the Italian poet Boccaccio to his well-known collection of tales. They are supposed to be instrated by a party of guests during a ten days' visit to a villa in the country, while the plaque raged in Roceance in 1849. There are flow works which have had an equal influence on literature with the Decameron. In linguand its effects works which have had the notion of the frame in which he inclosed his tales. the notion of the frame in which he inclosed his tales 623

from it; and, according to Burton, in his "Anatomy of Malanchot," one of the principal amosements of our ancestors was the reading of Boccassic sloud. The first English translation of the Decameron appeared in two

DECASTATION, do kins tail skins (Fr. decayler, to pour off), in Chem., a process of separating the solid and liquid constituents of sciutions, by allowing the immer to subside, and drawing off the latter by means of a siphon. It is resorted to in cases when the asid or alkaline nature of the solution would desirar a paper

or linen filter.

DECAPITATION. (See CAPITAL PURISHERS.) DECEMVIEL, de-sem'-vi-ri (Lat. decem, ten; piri, men), the title of certain magistrates or functionaries in an oient Rome, who were appointed as a sort of commission to draw up a code of laws. Three commissioners were first sent over to Greece, and the principal work of the Decemviri was to collect and digest the information gained by them. After a year's absence, he commissioners returned from Greece, and a wolsent dispute arose between the patricians and plebelans as to which party the decemvir should be chosen from. The patricians gained the day, and the entire government of the state was intrusted to them during the year for which they were to hold office. This form of government proved very successful, and the state was governed with justice and moderation. On the sonclusion of their term of office, a fresh body of decemvirit wise aboves, and the only one of the previous commission who was cient Rome, who were appointed as a sort of communication and the only one of the previous commission who was re-elected was the notorious Appins Cisudius. The new decempiri acted in the most unjust and transical new december acred in the most unjust and expansion manner. Each of the ten was accompanied in public by twelve lictors, who not only carried the rods, but the axe, the emblem of sovereign power. The plebsians were treated with every variety of contumely and outrage, until the unjust decision of Appins Chaudias in the case of Virginia seemed to bring the trygramy to a climar. The december were driven from their office. by a popular insurrection, and the cibunes and ordinary inagistrates of the republic were again appointed. Besides these extraordinary commissions, there were

Besides these extraordinary commissions, there were decenviri chosen for judicial purposes, to preside over and summon the centumviri, and to judge certain causes by themselves. Decenviri were likewise appointed at times to divide lands among the infiltery.

DECIMAL FRACTIONS, destinated frakt channel (Lat. decem, ten), are fractions which have 10, or same power of 10, for their denominator; as one tenth, one housandth, &c. In ordinary practice, it is often convenient to use decimal fractions, which, for the sake of brevity, are not written out fully. The numerator alone is expressed, with a point on the left-hand side: thus, 3 represents \( \frac{1}{2}\_{0.0} \). 30 represents \( \frac{1}{2}\_{0.0} \). 30 represents to have been introduced about the middle of the 15th century, by Regiomontanus. The first treating on the century, by Regiomontanus. The first treatise on the subject was written by Sterimus, in his "Practique d'Arithmetique," published in 1882. They are now generally adopted amongst all civilized nations in generally anopted amongst an averaged materials arithmetical calculations. In many countries the weights, measures, money, &c., are regulated and calculated by decimal division. Many arguments have been used, and many attempts have been made, to introduce a decimal coinage into this country, but

without success.

DECIMATION, des-im-ui-shun (Lat. decem; ten).—In former times, when an army, or any division of an army, had mutined against its commanding officer, and all had equally incurred the penalty of death, punishment was inflicted on the revolted troops by different periods. killing every tenth man, selected by lot, or taken out in the order in which they stood in the ranks. This mode of punishment was sometimes resorted to when a body

of punishment was cometimes resorted to when a body of men had shown cowardice before the energy.

DECES, deks (Ang.-Sax.), a term used in Mar. to denote the floors of a ship. Besides serving as platforms for the people on board, they keep the see and rain from the cargo beneath, and also strengthen the ship by holding her sides together. In large vessels there are several decks; namely, the origin deck, which is the lowest; the lower, or first deck; the middle, or second deck; the appear, or main deck; and the quarter deck.

DECLARATION, del'-lim-ai'-shun (Lut. declamere, to

## Declaration

speak sloud, to declati in public in the town an the Greeks, declarati-ferently on all subjects of making a thing arm pulse summary our test was things, and of pulse sower the best and condest reasons. Among many, a saming m. It was generally restricted is in creation which suboling perform at school, and them be appeal is public. "Declarations." Such as are usually pronounced in a sre, if but sadapted to real cases, and made to account pleadings, of the greatest service, not take our education has still to reach maturity for the series is alice both in conception and in arrange—that even when our studies are said to be combes our education studies are said to be comwas even when our studies are said to be comd. and have obtained us reputstion in the forum; of and have obtained us reputstion in the forum; of any other sort of diet, and is refreshed after fasting by the constant roughnesses of forensic that it is not of the second o shiftle dramatical performances of few scenes respeaking. Declamation forms, or rather we fear we must say would form, a most useful brauch of education, the charge of speech and action, the contract only correctness of speech and action, the contract of the contract of

Decreasion, dek-lär-ai'-shun (Lat. declaratio), Discrimation, dek-lin-al'-shun (Lat. declaratio), a legal specification on record of the cause of action by a plaintiff against a defendant. The declaration should correspond with the process in the names and descriptions of the parties; for if there be a material variance, the court will set aside the proceedings. The plaintiff may declare us soon as the defendant has appeared in wer to the writ of summons, or, where the summons is not specially indorsed, on failure of the defendant to make appearance. The declaration must state to make appearance. The declaration must state clearly the plaintiff a case in one or more counts, each count generally setting forth a separate cause of action. All irrelevant matter is struck out at the cost of the phintiff; and if no appearance is made by the plaintiff after the declaration has been delivered to him or his attorney, the plaintiff may proceed to claim judgment by default. (See Pleading.)—Ref. Tomins' Law Dickmary.

DECLARATION, an asseveration made in place of an oath. From time to time statutes have been enacted to enable Quakers, Moravians, and Separatists to make s solema affirmation that what they say is true, in graing evidence either in civil or criminal cases. False

collections are liable to the penalty of perjury.

Discrimination, Dying, a declaration made by a cross mader the conviction of approaching death. Such declarations are admitted as evidence at a trial, and are often very useful, although, as a general rule, hearing or secondary evidence is not allowed in English law. In cases of murder, the dying declaration of the victum a always admitted as evidence, if it can be proved that the deceased gave the evidence deliberately, and was in presention of his faculties. (See Evingence.)

Declaration, de-klen shun (Lat. declinatio, from decline, I dealine, bend, or deflect), in Gram., denotes the various modifications of number and case to which noins, pronouns, and adjectives are subjected, in order to sincess the relation which one thing hears to other things. To decline a noun, therefore, is to go through its several cases, singular and plural. (See Case, NUMBER, NOUN.)

Present, Notw.)
Descriptions, dek-lin-ni'-shun (Lat. declinare, to insine). The position of a star in the heavens is determined by its right ascension (see Ascension, Histor) and declination, as the position of any place on the earth's surface is determined by its latitude and implification. If we suppose a great circle to passes through any star in the heavens and the north and could pales, being consequently perpendicular to the compact, that portion of the circle which lies between the approach the panafor, whether it be north or south

to this affect at the life of that adacuterous and skilful
scaller extrem by his son. But shelves this he true or
rote, it is certain that the discovery was made about the
core of the 15th century, as incontestable widence
crists that it was known to the principal maritime
astions of hurope that were engaged in commerce at the
commencement of the century following. When the
commencement of the century following. When the
magnetic needle of the mariner's domplass is disturbed,
it oscillates until it gradually settles, and points sheadily
to two points on the horison, or presinted circle of
the instrument representing the horison, which are
dismetrically opposite to each other. A great circle
passing through these points in a plane-perpendicular
to that of the true horison, represents the magnetic
meridian of the place, while the geographical or astronomical meridian is represented by a great circle also
vertical to the horison, the plane of which pesses
through its true north and south points. These planes
intersect, and are inclined to each other at a small
augle, and this angle indicates the extent of the variation angle, and this angle indicates the extent of the variation or declination of the magnetic needle from the line joining the true north and south points of the horizon. declination may be either east or west, as the magnetic poles happen to be either east or west of the true north. The declination of the needle is constantly warring. In 1581 it was found to be 11° 15′ E. of the true north, from observations made near London; in 1833 it was only 4° 5' E.; while in 1657 it is said to have pointed due north and south; but the authority on which this assertion rests is doubtful. In 1818 it was found to be 24° 30′ W., and in 1822, 24° 12′ W. It seems, then, to be a fair hypothesis that the declination varies albeit. nately to the east and west to about 25° on either side, gradually returning from the maximum of variation on one side to the true meridian, and thence progressing to the maximum on the other side; and from other data given above it would appear that the rate of increase or decrease in the variation averages about 8 or 9' yearly, and that the needle takes about 170 years to arrive at either extreme of variation after pointing due north. But as very little is known, compersitively speaking, of terrestrial magnetism and its causes and effects, no hypothesis respecting the erratio movements of the needle can be received with safety or considered satisfactory. The declination of the needle at any place is so inconstant that it varies even in the course of the day, being sometimes cast and sometimes west of the early sering sometimes east and sometimes west of the mean variation at that place. The variation is ascertained and measured by an instrument constructed for the purpose, called a declinometer, and by the dipping-needle. (See Dipping-NEEDLE.)

DECOCTION, de-kok'-shur (Lat. decogno, I boil), in Chem. the astructure of the adults reserve the

Chem., the extraction of the soluble portions of plants by boiling or heating in water.

y boiling or heating in water.

Decomposition, de-kom-po-zish'-un (Fr. decomposer. to decompose, from Lat. compone, composites). This term is applied, in common parlance, to the separation of the constituents of a substance during patrelaction. In chemistry it is applied to any process during which a compound hody undergoes the separation or

re-arrangement of its elements.

DECOMPOSITION OF LIGHT. (See LIGHT.)

DECOMPOSITION OF FORCES. (See FORCES.)

DECORATED ENGLISH, dek'-o-rai-ted (Lat. decor. I adorn).—This style of Gothic architecture, also known as the Second, or Middle Pointed, or Edward. anown as the Second, or nothing to interest, or account, in, prevailed in England during the 1sth conduct, and was generally adopted in all ecclesiations and public buildings erected in the reigns of fitcher'd L. Edward II., and Edward III.; whence the term Edwardian has been assigned to it by Messra. Garbett and Fergusson. It corresponds with the atyle known as Ogical Secondaire in France, which expension is used in that country to denote the Gothic archithrough any star in the heavens and the north and south pulses being consequently perpendicular to the context of the context posterior of the circle which lies between the storage the equator, whether it be north or south of that irres, is the declination of the star. Declination circles are speall circles from on the celestial globe parallel to the sensitor, similar to lines of latitude on the terrestrial globe.

Decument any star in the heavens and the north or south to the property of the star of the

about the middle of this period. It is a be the most perfect of all the different say architecture. It possessed all the possible commentation of that which immediately commentation of that which immediately preceded in but there was a greater degree of sleguese in the outlines of the former, and more richness in the latter, which was bold and natural in design and execution, without being too florid and claborate, as in the succeeding period. Its chief characteristic features are the windows, the doorways, the capitals of the pillars, and the vaulting of the roots. In the windows the lancet and the valuing of the roots. In the windows he lanced from assumes wider proportions, and instead of consisting of one long narrow pointed light, or two or three of these at the utmost, grouped together and separated by plent, they are broader, and divided into live or more compartments by shafts or multions. The head of the window is still pointed, the area forming it being described either from centres taken without the sides, or from centres taken in the sides themselves, with a radius equal to the span of the window. The tracery of the head consists of cusped circles combined with geometrical curves, which are also foiled or ornamented with cusps. The piers and arches of the doorways are wishly ornamented, the former with light shafts sursounted with sculptured capitals, and the latter with deeply-cut mouldings. Both doors and windows have stones above them resting on corbels, which are frequently carred to resemble heads. Sometimes the moulding of the arch of a doorway is continued through the piers towards the ground, without any break at the impost from which the arch springs. Mouldings of every description are enriched with ball-flowers and Svery assembled are enriched with uni-nowes and bolings, and crockets are used to ornament the angular edges of pinnacles and canopies. The buttresses are bold and highly-finished, and flying buttresses are frequently used. The pillars are formed of groups of light and elegant shafts clustered together, and surveyed the annual property of a bell swelling out mounted by capitals consisting of a bell swelling out to a convex form from the neck-monlding, and deco-sated with foliage and flowers closely copied from the netural forms. The vaulting of the roof is subdivided into patterns, by ribs in different directions interlacing each other, so as to form a kind of rectilineal tracery, and besatifully-carved bosses are fixed at the points of intersection. (See Plate XLL.)

intersection. (See Plate XLL.)
DECOT, de-kot' (Ang. Nor.), a plan by which ducks
and other squatic birds are entired up a narrow channel from a river or lake. This channel usually terminates in a cover of network several yards in length. On either side of the channel the tur' is kept smooth and in good order; this tempts the birds to leave the water, and they alight and begin to dress their pluthage. While thus employed at some distance up the chainel, the decoy-man and his dogs, who have been on the look-out, but carefully concealed, suddenly appear. The birds take to the water again, and are driver by the dogs into the network inclosure, where they are mily captured.

Durans, de-kree' (Lat. decretum, from decerno, I judge), is the decision or order of some competent authority upon some doubtful or disputed point. During the Roman emperors it was usual to submit disputed points to them for their decision, which was called decretium, and became part of the Roman laws. In the Middle Ages, when the pope came to be regarded as the highest authority in ecclesiastical matters, his decisions, in like manner, were received as law, and took the name of decretals. (See Canen Law.) Les, she book the name of decretals. (See Canen Law.) In the lest of England the final judgment of a court of equity is usually called a decree; in Scotland it is applied to the final judgment of any of the courts: in the latter country it is also frequently termed a decreet.

Decress of Gop, in Theol., are the settled purposes of the Emighty, whereby he hath from all eternity: foreordained whatsoever comes to pass. (See Parassers arous)

Department, dedic infishers (Lais dedice, I works, definite), in Lit., is a complimentary dress to a particular person, profixed by an aut to tils work. The practice score from the si remaineration that in early many from literary labour. Hones suthers as in many cases dependent upon whether in many cases dependent upon whether works peand in whom they dedicated their works peand in whom they dedicated their works peand in the patronage of a p st in early times was to b wany antibors sought the pstronage of a pro-wealthy individual, by dedicating their works It thus came to be a common practice to achie

It thus came to be a common practice to acknowledge a dedication with a sum of money. Pretamately this state of things has ceased to exist, and there's rulent may be said in every case to find itself suitably rewarded by a discriminating public. Dedications have therefore in a great measure passed away, and whose we splitful them, they are generally either a trigon of private friendship or a mark of public exteem.

Dedication is a religious ceremony, whereby a person or thing is solemnly consecrated or act spatt to the service of God and the surposes of religion. The use of dedications is very ancient both among the worshippers of the true God and among the fashire. In Scripture we meet with dedications of the above the garments of the priests. Under Christianity, dedication is only applied to a church, and is naually called the consecration thereof. (See Consecration)

nacle, tomple, altars, vessels, persons, and svenof the garments of the priests. Under Christianity, dedication is only applied to a church, and is amady called the consecration thereof. (See Consecration).

DEDICATION, Frast Of, was a festival observed in the early church on the anniversary of the dedication of any particular church. The practice is said to have been established in England by Gregory the Great, who, in an epistle to Mellitus the abbot, gave injunctions to be delivered to Augustine that the people be allowed liberty on these anniversaries to build beeths and feast round their churches, in lieu of the ancient heathen sacrifices. This festival, or wake, as it was called, was long observed with much entenancy i had it ceased to be hell about the churches, but in private houses. A council held at Orford in 1222 ordained that, among other festivals, the day of dedication of every church should be observed within its preparable. In many places the observance was afterwards transferred to the Sunday following the day of dedication; and in 1536 Henry VIII. enjoined that it be kept in all places throughout the residen on the first Sunday in October. Afterwards the Puritans began to exclaim against it as a remnant of appeary, and popular prejudice was excited against it, so that in many parts it was discontinued. It is still observed in some parts of England, particularly the north and midland counties.—Ref. Hool's Church Dictionary.

Deduction, which consists in rising from particular truth to the determination of a general principle already known. It is opposed to induction, which consists in rising from particular truth to the determination of a general principle affects will fallow. Before we can deduce a particular ruth, we must be in possession of the general truth, which in the same thing agree with one in uses the former kind of truth, is demonstration or science; while truths drawn from the laster kind are contingent and relative, admitting of correction or science; while truths drawn from the l

or science; while truths drawn from the latter kind are contingent and relative, admitting of correction by increased knowledge. The mathematical and metaphysical sciences are founded on addanting the physical sciences rest on induction—Ref. Flemma's Foundation—Ref. Flemma's Foundation—Ref. cabulary of Philosophy.

DRED, dede (Sax. dad), a formal document, a

or parchment, duly signed, scaled, and delivered. When made by one party only, a deed is called a deed when made by one party only, a deed is called a deed poll; when several parties are concerned, an indentare. A deed poll is out even, or golled, at the edges. The form commences in the mode of a declaration,—"Enow all wen by these presents, that," &c. The form appropriated to an indenture, or a deed among several parties, is,—"This indentare, made, &c., bettern, &c., Witnesseth," &c. A properly extragged deed of conveyance usually congust of the following passars—Free.

## Deemstor

the date and names of the parties; are recitals in which the intentions of the p former transactions with regard to the ar-counted as far as necessary. Then the oper countsing of the habondum, which defines or lease reserving rent; the material upon or lease reserving and the parties and the parties are reconsisting of the habendam, which defines the estate or interest to be gravited; the tenendam, usually joined with the laboudamy, but it is unnecessary, since the tenent is more expressed, a recept upon or lease reserving rent; the material upon the tenent material to the parties. or increase to be granted; the communication is usually joined with the independent, but it is nunceessary, since the tenure is never expressed, except upon a sub-grant or lease reserving remy; the suddendum, or the reservation of some new tining, such as rent to the grantor; next some the consistions; if any, annexed to the grantor; next some the consistions; if any, annexed to the grantor; next some the consistions of the consistion, which mentions the exception. As A deed must be signed and sealed by the consistence and by the granter and by the granters are the granters and by the granters are the granters. the granter, and by the grantee also, if any agreement or command is entered into by him. The delivery of a or or smart is entered into by him. 100 dearch, and deed completes its efficacy, and thence it takes effect.

A deed in good although it mentions no date, or has a or impossible date, provided the real date of its delivery can be proved. After execution, a deed may become void by erasure, interfineation, or other alteration in any material part; but, generally, such alterations are presumed to have been made before execution.

pever found in localities even where it is certain that hundresis of antiers must have been shed. This, how-ever, is not the only instance of the mysterious dis-appearance of cessons matter. In the torests of Ceylon, appearance of oresone unities. In the forests of Cepton, where hundreds of elephants mans disk in the owners of a single year, the skoiston of that gigantic animal is, as is, related on eminent authority, more found. (See ELEPHANT.) The species of Cervicia are very numerous, and dispersed generally through the world, excepting Australia and the south of Africa. Dear are pretty uniformly clothed with hair longer and thicker on those which inhalt cold than those which inhabit incided. which inhabit cold, then those which inhabit hat the mates. The ancient customs and laws of "veneric." that noble science which our ancestors looked upon as one of the first accomplishments of the high bred not and a knowledge of which was essential to his advanta were formal and technical to a most shourd degree few of the terms betokening the different ages of the stag and hind are still retained, though somewhat altered. The young of either sex is called a calf. After a few months the male becomes distinguished by the growth of the bossets, or frontal protuberances on which the horns are afterwards developed, which, during the first year, are merely rounded knobs; from whence he takes the name of "Knobber." In the ascound year they are longer and pointed, and are called dags, and the animal has now the name of "Brocket." In the third year, the first, or brow autler, has made its appearance, and the deer becomes a "Spayad." In the fourth the bes audier is added, and he is then termed a "Staggard." He is a stag in the fifth year, when the third autier, or "Royal," appears; and in the sixth, third autier, or "Royal," appears; and in the sixth, the commencement of the sur royal, or crown, is formed. when he takes the name of hart, and retains it through his life. At this time he is called a hart or stag of ten. probably because the branches, including the sur royal, irequently amount to that number. After the seventh year he is said to be croched, or pulmed, or crowned, according to the number of branches composing the sur royal. The female is a calf in the first year, brocket's sister in the second, and in the third, and afterwards, a hind.—Ref. Bell's British Quadrupoile.

Dremous, deer none (Meriones), a gen. of Ameri-

can rodent quadrupeds. The deermouse is common in Camada. It is about the size of a mouse, with a very long tail, and very long and slender hind legs. It is capable of making leaps of four or Aveyards. It burrows, and passes the winter in a lethargic state.

DEER-STALKING, stank'-ing (Sax. stateon, to step slowly), a method of hunting the deer in such wild and precipitous countries as render the pursuit of them with dogs and horses impossible. It is a very favourite sport in Scotland, and it requires in the sportsman patience, perseverance, and exertion, being at the same time attended with no slight amount of danger, through the nature of the localities where the game is found. The localities of deer-stalking are principally confined to the Highlands of Scotland, and coursequently embrace some magnificent scenery. stratagems of deer-stalkers to get within reach of their cautious prey are very varied. The extreme wariness cautious prey are very varied. cautious prey are very varied. The extreme wariness of the red deer is such that it requires the atmost circumspection to advance towards them. When they are approached, it must always be done on the leaward. side, as the quick scenting powers of the deer would soon apprise him of the presence of a sportaman who came on the windward side. A circuit of some miles is often necessary, in order that the statkers may approach the deer undetected. After having arrived at the given point, it is often found necessary to gain another completely concealed from the wary sentinel of the herd, one being always especially on the look out to goard the whole against surprise. It is necessary, therefore, that the stalking party in those cases should lie down until the herd have turned into another situation. The best rifles are used in the sport, and the dogs employed are well bred and thoroughly trained to the work. Two or three couples are required, and they exe

### Defamation

has no legal right to the same; in which sense it is opposed to a king de jure (of right), who has a right to a crown, but is out of suspension.

DEPLIMATION, def-d-moi-chus (Fr. diffusier, to define, from Lat. diffusio), in Law, is when a person speaks scandalous things of another, as of a magistrate, whereby the person spoken against suffers in repu-tation. The party so offending is liable to be punished according to the nature and quality of his offence; secording to the nature and quality of his offsee; sometimes by action on the case at common law, sometimes by statute, and sometimes by the coclesiastical laws. In some special cases, defamation is punishable in the spiritual courts. (See Labre, Siander.)

Berauch, de-fault (Fr. defaul), in Law, generally signifies the non-performance of that which enght to have been done. In a special sense, however, it denotes the non-performance in court as a day assigned.

the non-appearance in court as a day assigned. A plaintiff is nonsuited who makes default in appearance in a trial at law; and judgment may be had against a defendant who makes default.

DEFENCE, de-fens' (Fr. defendre, to oppose or deny), in Law, signifies popularly a justification or protection This was, however, not its original signification, as its Tass was, nowever, not us original signification, as its French derivation shows; it merely meant an opposing or denying by the defendant of the truth or validity of the plaintill's complaint. A defence is in reality a general assertion that the plaintill has no ground of action, which assertion is afterwards extended and excitations in the defendant plan.

DEFENDATE, defended in the defendant's plea.

DEFENDATE, defended in the desirable from tendent in a personal action. It is distinguished from tendent, the party sued in a real action. The term defendant is also used to designate the person indicted or otherwise proceeded against for any crime not amounting to felony.

DEFENDER OF THE FAITH, de-fen'-der, a title conferred by Pope Leo X. on Henry VIII, for writing against Martin Luther in 1921. Though subsequently recalled by the pope, it was confirmed by act of parliament, and has ever since been retained by the sove-

reigns of this country.

DEPLADING dessibilities of constructing works of defence, in such a manner both as regards the direction and height of the lines of rampart, that no portion may be enfi-laded, or swept a ong its entire length by a fire from any eminence commanding the fortification, and that the parapet of the ramport may be high enough to prevent the interior from being exposed to the direct fire of the enemy. The former is called horizontal and the latter enemy. The former is called horizontal and the latter vertical defilading. DEFILE, de-file\* (Fr. defiler, to march in file), the name givon in Mil. to any narrow passage, whether it

be a deep valley between two hills, a road between

be a deep valley between two hills, a road between hodges, or even a street, along which troops can only march in column with a narrow front.

DEPINITION, def-e-visib-an (Lat), literally signifies the laying down a boundary, and is applied to the giving or explaining the meaning of a word by means of other words. A definition serves to show what notions are to be included, and, by inference, what to be rejected, in each word; and thus to afford as far as possible, a precise understanding of its meaning. Definitions are usually distinguished into nominal and real; the former merely explaining the meaning of real; the former merely explaining the meaning of terms, and thus belonging to grammers and diction-aries; the latter explaining the nature of the thing itself, and coming within the province of logic. Real definitions are divided into essential and accidental; the former stating the primary and essentially con-stituent parts of that which is to be defined; the latter laying down what are regarded as circumstauces or laying down what are regarded as circumstances or properties belonging to it. Essential definitions are again divided into physical and logical, the former enumerating such parts as are actually separable, the latter the separate ideas in the mind that go to complete the abstract notion represented by the word; namely, the genus and the difference. The conditions of a good definition are:—1. That it be adequate, neither too narrow, and thus only applicable to a part instead of a makely size too extensive, to include a whole instead of narrow, and thus only spheroist or plant in the whole, nor too extensive, to include a whole instead of spart; 2, that it be clearers, e., consisting of ideas less complex than the thing defined; and 3, that it be expressed in a suitable number of words, in opposition person for ever of a dignity or degree of honour. The te prolixity, or excessive brevity. Words expressive of degradations of a peer, priest, knight, efficer, &c., are

## Degradation

ideas purely simple cannot be properly defined, and words expressing less-complicated ideas are from their nature more perspications than those which express the more complex ideas.

DETLACHARION, def-lit-grai-skur (Lat. de, concerning; flagro, I burn), is ordinary language, a rapid combustion attended with flame and vapour. The term, however, is generally applied to the sudden combustion of substances by throwing them into a red-hot

cracible.

Deplexion of Rays of Light. (See Light.)
Devoemery, de-form'-e-te (Lat. deformities, from de, and forma, a form), is the want of that regularity of form necessary to constitute the beauty or symmetry of an object. In the human subject deformities may be either congenital or acquired; i. s., occurring before or after birth. The subject of congenital deformation has recently received from medical men a great degree of attention, and is usually treated of mader the head of Teratology (Gr. teras, a monster, and logas, discourse), a term introduced by Geoffroy St. Hilaire. Formerly various absurd notions were entertained on this subject, and a monstrosity was considered as the presage of some misfortune, the warrant of divine ven-geance, the effect of witchcraft, &c. To these notions they owe their name of monsters, from the Lat. mor strure, to show. Modern rescarch has shown that these deformities are all to be traced to natural causes. which are generally reduced to two main divisions,—1, to the original malformation of the germ; or, 2, to the subsequent deformation of the embryo by causes operating upon its development. To the former class operating upon its development. To the tormer cases are attributed such malformations as are repeatedly produced by the same parents, and hence are in some degree hereditary. Subsequent deformation of the embryo may be produced by various causes affecting its development. A very prevailing opinion is that deformities may be occasioned by strong mental impressions on the much of the female during pregnancy. Of this, however, there is no satisfactory proof, and it is generally discredited by medical men. Deformities, however are frequently moderal by invisical injuries however, are frequently produced by physical injuries suffered by the mother during pregnancy; and hence a strong mental impression may so affect the mother physically as to transmit its effects to the fortus. A third cause is attributed to diseases of the ovum and fotus. A fourth, and assuredly a very general and requent cause of malformation, consists in impeded development of the fætus by some remote and unknown cause. Those who wish to investigate this subknown cause. Those who wish to investigate this subject further will find a long and able article upon it in Todd's "Cyclopædia of Anatomy and Physiology," under the head Teratology. The various kinds of artificial deformities will be found treated of under

their proper heads in other parts of this work.

DEFTER-DAM, def'-ter-dar (Persian), signifies, literally, a book-keeper, and in Persia and Turkey is the title of the minister of finance. In Turkey he site in the divan, disposes of all the public money, and pub-lishes firmans in his own name, without referring to

the grand vizier.

Digitation, deg-loo-tisk-un (Lat. deglutitio, from deglutio, I swallow), is the act of swallowing, or the passage of a substance, either solid, liquid, or gaseous, from the mouth to the stomach. Though simple in appearance, deglutition is yet the most complicated of all the muscular actions that serve for digestion. It is effected by the contraction of a great number of muscles, and requires the concurrence of many im-portant organs for its accomplishment. It is divided into three stages. In the first, the food passes from the mouth to the pharynx; in the second, it passes the opening of the glottis, that of the nasal organs, the opening of the glottis, that of the nassi organs, and arrives at the onsophagus; and in the third it passes through this tube and enters the stomach. The first of these is purely voluntary; the second is not so, but is an action of the reflex function; the third is altogether involuntary, being due to the irritability of the exophagus, which, by a series of muscular contractions and expansions, forces the substance decreases.

all performed with divers beremonies. In the Church of England a clergyman may be denrived of the holy orders which he formerly had, either summarily by werd only, or solemnly, by divesting the party degraded of those robes or ornaments which were the ensigns of his degree. By canon 122, sentence of deposition from the ministry can only be pronounced by the bishop, with the assistance of his chancellor and the dem, if they can conveniently be had, or certain others. In the Romish church the person to be degraded appears before the priest who is to perform the ceremony in his clerical vestments; those parts of the hands which clerical vestments; those parts of the hands which had been anoisted are first slightly scratched with a knile or piece of glass; he is then successively stripped of his sacred or paments and robes of office, is clothed in a lay hebit, and then publicly handed over to the secular judge, who is present to take him under his jurisdiction.

DEGREE, de-pree' (Lat. de, of or concerning; gradue, a step; Fr. dégre'), in universities, is a distinction conferred on the students or members of a university as a testimony of their proficiency in the arts or spiences, and entitling them to certain privileges. The origin of degrees, like many other points connected with the early history of universities, is involved in obscurity. That they existed at a very early period is unquestionable, but there is no reason to believe that they were co-eval with the earliest universities. The oldest degrees were those in arts; and the term bachelor, which designates the lowest degree in each faculty, would seem to justify us in tracing the whole system of degrees to the university of Paris. The terms master and doctor were originally synonymous, and were commonly given to persons engaged in teaching, and not as titles conferred by authority after a prescribed course of study or a formal examination. Afterwards the term master was restricted to teachers of the liberal arts, and the title of doctor was assumed by the teachers of theology, law, and medicine. The masters and doctors afterwards adopted certain regulations, which were confirmed by public authority, to prevent unqualified persons from assuming their office; and hence these titles came to indicate a certain rank, and convey certain powers in the body scholastic. When this took place, and more especially when an initiatory stage was marked by the name of bachelor, the several designations were called steps, or degrees (Lat. gradus). Every graduate had an equal right of teaching pub-Every graduate had an equal right of teaching pun-licly in the university the subjects competent to his faculty up to the rank of his degree, and he even in-curred an obligation to teach as a condition on which his degree was granted. Degrees are of two kinds; I. Ordnary, or those which are conferred upon the members of a university after examination, and are thus certificates of attainment; and 2. Honorary, or those that are sometimes conferred upon persons of distinction without any examination. Degrees bear distinction without any examination. Degrees bear the same names, and, with some variation, the same relative academical rank, in most countries of Europe; remains accommend rank, in most countries of Europe; but the mode of granting them, and their value at different universities as tokens of proficiency, vary greatly. In the English universities there are few artist the degrees of bachelor and master, and for the higher faculties bachelor and doctor. The degree of doctor faculties bachelor and doctor, of the finite manner. faculties bachelor and doctor. The degree of doctor in philosophy, granted by some of the foreign universities, is of modern introduction.—(See Universities, and the several articles on special universities; as those of Cambridge, London, Oxford, &c.)—Ref. Encyclopadia. Britannica, art. Universities.

Degree.—In Math., the circle is divided into 60 equal parts, called degrees; each degree into

60 equal parts, called degrees; each degree into 60 equal parts, called minutes; each minute into 60 seconds, each second into 60 thirds; and so on. (See Cracts, Thiscorometers). In Astron. and Geogr., the imaginary great circles that are supposed to be described on the surface of the earth, and on the apparent surface of the heavens, are similarly divided, to sid us in effecting astronomical and geographical calculations, and in determining the position of stars and other celestial bodies on the latter, and the struction of theses on the former. These divisition of stars and other celestral boutes on the inder-and the situation of phaces on the former. These divi-sions are known as degrees of latitude and longitude, according to the direction in which they are measured. Degrees of latitude are measured from the equator towards the north and south poles, along the meridian,

or any great circle in a plane perpendicular to that of the equator. They are numbered, in either direction from the equator, from 0° to 30°. As the earth is not a complete sphere, the length of a degree of tatitude is not exactly the same at all parts of the earth's surface, being rather less at the equator than at the poles; for being rather less at the equator than at the poles; for all practical purposes, however, they are assumed to be equal everywhere, having a mean length of 60 geo-graphical miles, or 691 English miles, which would be the case if the earth were spherical instead of being an oblate spheroid. The small circles which are sup-posed to be described on the earth's surface through every degree of latitude, in planes parallel to that of the equator, are called parallels of latitude. Degrees of longitude are measured east and west along the equator, from the meridian of Greenwich on the ter-restrial globe, and from the first point of Aries on the celestial globe, and are numbered in either direction from the points that have been indicated from 0° to 180°. Each degree of longitude is 60 geographical miles, or 60°1 English miles at the equator. It may be defined as the arc intercepted between two meri dians or great circles that intersect each other at the poles at an angle of 1°. It will readily be seen, that as the meridians are at 60 geographical miles' distance from each other at the equator, and meet in a point at the poles, the degrees of longitude recome less and less in length as they are measured along every suc cessive parallel of latitude between the equator and the poles. The following table shows the length of a degree of longitude in English miles measured along every fifth parallel of latitude,—the distance at which parallels of latitude are usually inserted in maps of ordinary size. The table is calculated on the supposition that the earth is spherical.

Deg of Lat.	Eaglish Miles.	Deg. of Lat.	English Miles.		English Miles.
0	69:10	; 35	56.51	70	23 60

20	64.84	55		90	., 0.00
25		60			
30	59.75	65	. 29.15		

It should be remembered, that in describing the position of a place on the earth's surface we must mention the latitude as north or south of the equator, and the longitude as east or west of the first meridian. In most countries geographers assume the the meridian of the capital as the first meridian.

DEGREE, in Mus., a name given to each line and space contained in the staff. There are nine degrees; viz., five lines and four spaces; when a greater number are required, short parallel lines, called ledger lines, are added, either above or below the staff. A melody is said to proceed by degrees when it ascends or descends to the next line or space.

DEGREE, THEORETICAL, in Mus., the difference of position or elevation between any two notes. retical degrees are of two kinds, viz., conjunct and disjunct; they are called conjunct when two notes are so situated us to form the interval of a second, and disjunct

when they make a third or any greater interval.

DEGREES OF NOBILITY. (See NOBILITY.)

DEI FLATION. (See APOTHEOSIS.)

DEI GRAITA, de-ig-qui-sheo-il (Lat., by the grace of God), is a formula which sovereigns add to their title, and which is taken from an expression of the apostle Paul in the New Testament. It was first used by the clergy in the time of Constantine the Great, as an ex-pression of dependence upon the grace of God, and afterwards the higher clergy came to use along with it the addition, et apostolice sedis (by the grace of God and the apostolic see). In the time of the Carlovin-gian race the secular princes also assumed it; and in course of time it came to be regarded as asserting something like the divine right of kings and their in-

dependence of any earthly power.

Deinachida, dinā-kri-dā, a gen. of the Cricket tribe, abundant in New Zealand, where it inhabits decaying trees and chinks and cramies in old woodwork.

It is carnivorous, and its bite is very severe.

DEIPNOSOURISTS, dipe-nos'-o-fiets (Gr. deipnon, a feast, and sophistes, a sophist), was a name given to

## Deiscal

an ancient sect of philosophers famous for their learned conversation at meals. Athenens has left a collection of Ana, which bears the title of Deipnosophista.

DESCAL, de-is-kal, the name of a ceremony originally used in the Druidical worship of Britain, and consisting of the Druids, accompanied by all the worshippers, ing of the Pruids, accompanied by all the worshippers, proceeding from east to west, according to the course of the sun, three times round the alter. It invariably formed part of the public offices of their religion, and was preserved as a ceremony on various occasions long after Druidism had disappeared. In some parts, even down to a late period, it was customary for the people to testify their respect for their chieftain by restricting this ceremony round his passen.

performing this ceremony round his person.

DRISM, or THEISM, de'-izm (Lat. deus, Gr. theos, God), properly means belief in a God, as opposed to Strictly speaking, the two words are synon-Atherem: Strictly speaking, the two words are synon-ymous, but custom has made a distinction between them, the former being generally used in a bad, the latter in a good sense. In this view a deist is one who latter in a good sense. In this view a deist is one who believes only in a supreme being, rejecting Christianity and denying revelation. A theist, on the other hand, is applied to all that believe in one God. The name of Deist seems to have been first assumed as the denomination of a party by some gentlemen in France and Italy about the middle of the 16th century; and what tany about the middle of the loth century; and Viret, an emineat reformer, in his opisite dedicatory prefixed to the second volume of his "Instruction Chrétienne," published in 1563, mentions certain per-sons who called themselves by a new name,—that of Deists. These persons were desirous of disguising in Lensis. These persons were desirous of disguising in this way their opposition to Christianity under a more honourable title than that of atheist. The first deis-tical writer of any note that appeared in this country was Herbert of Cherbury, who flourished in the 17th century. He was the first to form deism into a system, asserting the sufficiency of natural religion, and hence discarding revelation as uscless and unnecessary. The five fundamental articles of his system were:—1. That there is one supreme God; 2. that he is chiefly to be there is one supreme God; 2. that he is chiefly to be worshipped; 3. that piety and virtue are the principal part of his worship; 4. that we must repent of our sins, and if we do so, God will pardon them; and 5. that there are rewards for good men and punishments for bad men, both here and hereafter. Among the more noted of those who have followed in his steps may be mentioned Hobbes, Blount, Teland, Collins, Woolston, Tindal, Morgan, Chubb, Bolingbroke, Hume, Gibbon, Paine, and, we may add, Lord Shaftesbury. In France, Voltaire, Rousseau, Condorcet, and many others, have rendered themselves compicuous by their deistical writings. Dr. Clarke distinguishes four kinds of deistes —1. Those who believe in the existence of an infinite and eternal being, who created the world withinfinite and eternal being, who created the world with-out-concerning himself with the government of it. 2. Those who believe in the being and natural providence of God, but deny the difference of actions as morally good or evil, which is merely established by human laws, God taking no concern with them. 3. Those who, having right apprehensions concerning the nature, attributes, and all-governing providence of God, yet consider them as of such a nature that we can form no true judgment nor argue with any certainty regarding them, denying the immortality of the soul, and alleging that the present life is the whole of human existence. And 4. those who believe in the existence, perfections, and providence of God, the obligations of natural religion, and a state of future retribution, on the evidence of the light of nature, without a divine revelation. Deism has assumed various forms, usually taking its character from the age in which it was. At one time it denied the historic evidences for the truth of Christianity; at another, the credibility of miracles; again it donied the necessity or possibility of a revelation, and amon the character of the revelation itself. Formerly desim was a rude, repulsive creation, destroying the distinction between right and wrong, depriving man of all hope of a hereafter, and giving him no aim for life but sensual pleasure. Now it has assumed a more pleasing and seductive form. The Bible is indeed a revelation, but it is such a revelation as is to be met with in other works; the writers were inspired, but it is such an inspiration as characterizes men of genius in every age. Minos and Moses were equally inspired to make laws, David and Findar to write poetry, Newton

## Delirium

and Isaiah, Leibnitz and Paul, had each only various forms of the one spirit from God most high. (See In-

forms of the one spirit from Grou most night.

SPIRATION, REYELTOR, RATIONALISM!

DEL CREDERE COMMISSION, del kred'-e-re, is a phrase borrowed from the Italian, and employed in mercenticle law to denote an additional premium charged by a factor or agent, in consideration of which he guarantees and the headman per-

factor or agent, in consideration of which he guarantees the solvency of the purchaser, and thus becomes personally liable for the price of the goods sold.

DRIEGATE, (See DRIEGATION,)
DRIEGATE, COURT OF, del'-c-gails, was formerly the highest court of appeal in ecclesiastical and maritime causes in England. This court was created by Henry VIII. for the purpose of hearing appeals from ecclesiastical courts, a right which had proviously been abled by the none. It was acculad because the indees beld by the pope. It was so called because the judges had delegated to them their powers by commission under the great seal. In ordinary cases, it was composed of three common-law judges and three civilians, but in special cases a fuller commission was sometimes

but in special cases a fuller commission was sometimes issued. This court was abolished by 2 & 3 Will. IV. c. 92, and its powers transferred to the king in council. By 3 & 4 Will. IV. c. 41, its powers are now exercised by the judicial committee of the privy council.

Delegation, del-e-gui-shun (Lat. delegatio, from delega, I refer, or commit to), is properly the investing one with authority to act for another, and has hence come to be applied to a body of persons deputed thus to not. Heaves the present oversity tion of the United to act. Before the present constitution of the United States of America was adopted, the persons consti-tuting the congress at Philadelphia were called dele-gates; and the body of representatives of a state in congress are still called the delegation of a state. In Maryland and Virginia, what in most of the other states is called the House of Representatives is there called the House of Delegates. The name of delegate is also given to the representatives sent to the congress. also given to the representatives sent to the congress of the United States from territories not yet formed into states. In the States of the Church, in Venice, and Lombardy, the term delegazione is applied to the governing court of a province as well as to the province itself. Prior to the recent political changes in Italy, there were nine delegazioni in Lombardy and eight in Venice, each of which was presided over by a delegate, a vice-delegate, and an adjunct. By a decree of 1816 the Papal States were divided into seventeen delegations; but this number has been several times altered. The delegate, according to the old system, must always be a prelate, and is appointed directly by the pope. If a cardinal, he has the title of legate, and his province is called a legation.

DELF, or DELFT, delf, a kind of coarse porcelain, originally manufactured at the town of Delft, in Holland. It has been superseded, even in Holland itself, by the superior manufactures of England, and the improved taste in the making of pottery introduced by Wedgwood. The town of Delft has now entirely lost its reputation for pottery; at present, not more than two hundred persons are engaged in the earthenware

factories.

factories.

Deliquescence, del-e-kwes'-ens (Lat.), the property possessed by certain substances of absorbing water from the atmosphere and becoming liquid in it. Advantage is taken of this property in the case of chloride of calcium, which is much used by chemists for drying gases, and for promoting the crystallization of other less deliquescent salts. The damping of com-mon salt in wet weather is an instance of the deliquescent property of the chloride of magnesium always contained in it as an impurity.

DELIRIUM, de-lir'-e-um (Lat. from deliro, I rave or am furious), is a confusion of ideas, which occurs in the progress of certain diseases, from dicturbed fun-tion of the brain. Sometimes the term is employed to include every form of mental alienation; but generally a distinction is made between insanity and delirium, the latter occurring principally in fever and inflammatory diseases, while the former is unattended by these disorders. (See Insantry.) The insane usually display all the external appearances of health, and have the digestive and nutritive functions in a sound state. In the delirious, on the other hand, all the cerebral functions are severely affected; there are no correct sensations, connected ideas, or passions; no regular voluntary motions; little or no intelligence or

820

#### Delirium Tremens

The patient is almost a stranger to everything that surrounds him, as well as to himself. Delirium may be either violent and frantic (delirium Jenium may be enter votent and transc transcripers.), see in acute inflammation of the membranes of the brain, or low and muttering (typhonamis), as in low fever. It supervenes on fever during my part of its course. It cocurs in the hot state of some intermittents, but rarely makes its appearance in typhoid or continued fever until the disease has reached its or continued fever until the disease has reached its height. It sometimes occurs suddenly, without any previous indication; but more frequently it is preceded by headache, throbbing of the temples, a flushed and oppressed countenance, &c. The patient is at first delirious during the short and imperfect periods of sleep, or immediately after he is roused, becoming, when fully awakened, more clear and comparatively collected. By degrees this incid interval becomes less bereentible: the individual becomes more and more perceptible; the individual becomes more and more incapable of reflection and mental exertion, and gradually loses the power of recognizing the persons and to terminate fatally, sensibility becomes more and more impaired, until all conscious feeling seems to be lost. Inarticulate mouning succeeds to delirious incoherence, the patient loses in a great measure sight and hearing; the mouth and tongue are dry, yet the patient no longer complains of thirst; the pupils become scarcely contractile; black spots, like flues, appear before the patient's eye, and the exacuations exceen without consciousness. A deliving is rether a escape without consciousness. As delirium is rather a symptom of disease than a disease itself, its treatment necessarily forms part of that of the disease on which it supervenes, and will therefore fall to be noticed

under these heads. DELINIUM TERMENS, DELIRIUM EBRIOSITATIS, or MARIA A POPU, is a disease of the brain usually caused by an abuse of spirituous liquors, but sometimes also by great mental anxiety and loss of sleep; or it may result from bodily injuries or accidents, loss of blood, &c. Delirium sometimes makes its appearance in consequence of a single debauch; but more frequently consequence of a single account in the interface of it is the result of protracted or long-continued intemperance. It usually supervenes on a fit of interfacion, but it not unfrequently occurs, also, when the habitual drankard omits his accustomed draught. The approach of an attack is almost invariably preceded by the patient being remarkably irritable, with fretfulness of mind and mobility of body. He becomes very nervous and uneasy; is startled by any sudden noise, the opening of a door or the cutrance of a visitor; is restless; the hands and tongue are tremulous; he complains of inability to sleep, and if he dozes for a moment, he is awakened by frightful dreams. Soon delirium manifests itself: if questioned, the patient often answers rightly enough; but if left to himself, he begins to talk or matter; he is surrounded by frightful or loathsome animals; is purstarding the property of the start of the start of the steerible and ghastly visions. Though most commonly of a frightful or terrifying character, the delirium is not always so: occasionally the appearances are droll and Indicrous, and the patient seems amused by them; at other times it turns on some matter of business, as settling of accounts or telling of money, and the patient is in a perpetual bustle, and his hands are constantly fall of business. The predominant emotion with the delirious patient is fear, and in his efforts to escape from an imaginary enemy, he may be guilty of a murderous assault, or, as is more frequently the case, may take his own life; and hence he requires to be very carefully watched. "The strong features of this complaint," says Dr. Watson, "are skeplessness, a busy but not angry or violent delirium, constant chattering, a trembling of the hands, and an eager and fidgety employment of them. . The tongue is moist and creamy; the pulse, though frequent, is soft; the skin is perspiring, and most commonly the patient is drenched in sweat." The delirium continues until the patient sinks into a sleep, from which he awakee comby them; at other times it turns on some matter of

## Delivery

fatal, unless where the etrength of the patient has been seriously impaired by long continued excesses. The great remedy is sleep, and the best means of inducing this is by opium, which is to be given in large doses, and frequently repeated, until the desired effect follows. Sometimes it is necessary, in order to procure sleep, if the patient is in a very exhausted state, or if the disease has been brought on by the creation of an accustment of the contract of the co accustomed stimulus, to allow the patient a certain quantity of his ordinary beverage; but this should not be continued longer than he can do without it. Chloroform has also been recommended as a means of procuring sleep when opium fails. This disease is to be carefully distinguished from inflammation of the brain, with which if her name armorous in comment. with which it has many symptoms in common; for bleeding, which is resorted to in the latter disease

would be of the utmost danger in this.

DELIVERY, de-liv'-or-e (Fr. déliver, to deliver), is the fifth and last of the several parts that go to make up the business and art of the orator, the others being invention, disposition, embellishment, and memory: invention, in order to find out what to say : disposition, invention, in order to find out what to say; disposition, in order to strange in a proper manner; embellishment, to deck it in proper language; memory, to retain it; and delivery, to give it forth with dignity and grace. The ancient masters of oratory looked upon delivery as occupying a most important place in the art. It is said of Demosthenes that when asked what was the first point in contract, he would be supported to the said of first point in oratory, he answered, delivery; and the second, delivery; and the third, still delivery. "Delivery," says Cicero, "has the sole and supreme power in cratery. Without it a speaker of the highest mental capacity can be held in no esteem; while one of moderate abilities, with this qualification, may surpass even those of the highest talent." Though, from the Though, from the character of the people and of the times in which we live, delivery may not now be entitled to the same attention that it formerly received, yet it only requires a little consideration to see that it is one of importance to the public speaker, and is entitled to a much greater degree of attention than it at present receives. If the end of all public speaking is to persuade,-to convey our own ideas and emotions to those whom we address, then our voice, looks, and gestures interpret our ideas and emotions not less than words do,-nay, the impression they make upon others is frequently much greater than any words can make. An expressive look, a passonate cry, often speak much more eloquently than any words. Words are only arbitrary conventional symbols of our ideas; but tone and gesture are the language of nature. "Every emotion of the mind," says Cierro, "has from nature its own peculiar look, tone, and gesture; and the whole frame of a man, and his whole countenance, and the variations or his voice, sound like strings in a musical instrument, just as they are moved by the affections of the mind." Apper, for instance, assumes a parof the mind." Anger, for instance, assumes a particular tone of voice,—acute, vehement, and with frequent breaks; violence has another tone, strained, quent breaks; violence has another tone,—strained, vehement; impetuous, with a kind of forcible excitement; fear is desponding, hesitating, abject; lamentation and bewading, flexible, full, interrupted, in a voice of sorrow; pleasure, unconstrained, mild, tender, cheerful, languid; trouble, a sort of gravity without lamentation, oppressed, as it were, with one heavy uniform sound. "On all these emotions a proper gesture ought to attend; not the gesture of the stage, expressive of mere words, but one showing the stage, expressive of mere words, but one showing the whole force and meaning of a passage; not by gesticulation, but by emphatic delivery, by a strong and manly exercise of the lungs; not imitated from the theatre and actors, but rather from the camp and the palestra." The first great object with every public speaker should be to speak so as to be fully and easily understood by all who hear him; and in order to this, the four chief requisites are a due degree of loudness and creamy; the pulse, taongn frequent, is solt; the cour chief requisites are a due degree of loudness skin is perspiring, and most commonly the patient is discussed. The delirium continues until the patient sinks into a sleep, from which he awakes comparatively rationals, or dies from exhaustion. In such cases death is often sudden, the patient rising for some trivial purpose, and falling in a faint, from which he never recovers; or at length, after passing many pights without sleep, he sinks into a state of come, which the suddent thing in a speaker is diswitted the comparatively such as the four chief requisites are a due degree of loudness skin is to exhibit the patient in the four chief requisites are a due degree of loudness of vice is doubtless, in good patient sinks into a sleep, from which he availes comparatively rationals, or dissinct on the four chief requisites are a due degree of loudness of vice, distinctness, allowness, allowness, and propriety of pronunciation. 630

#### Delphin Classics

pronounces, be distinctly heard; and attention to this will do more to compensate for loudness than is commonly imagined. In the 'third place, slowness of speech is to be studied; for the opposite confounds all articulation and all meaning. It gives weight and dignity to the discourse, and is of great assistance to the voice, by the pauses and rests which it affords. It also assists the speaker in preserving a due command of himself; whereas a rapid and hurried manner is apt to excite that flutter of spirits which is the greatest enomy to correct delivery. The speaker must, in the fourth place, attend to propriety in pronunciation, or the giving to every word which he utters that sound which the most polite usage of the language appropriates to it. There are other points that require to pronounces, be distinctly heard; and attention to this priates to it. There are other points that require to be attended to by all who would speak with grace and force, so as to please and move the audience; the chief of which are emphasis, pauses, tones, and gestures. On the right management of the emphasis depend the whole life and spirit of a discourse; and by an abuse of emphasis the meaning is often rendered ambiguous or perverted. In order to acquire the proper management of emphasis, the great rule is for the speaker to study to attain a just conception of the force and spirit of what he is going to say. The most frequent and principal use of pauses is to mark the divisions of the sense, and, at the same time, to allow the speaker to draw breath; and the proper adjustment of them is one of the nicest and most difficult accomplishments in delivery. Tone consists in the modulation of the voice, the notes or variations of sound which we employ in public speaking. Of the importance of this we have already spoken. A speaker cannot successfully convey his own sentiments and emotions to his hearers, unless he utter them in such a way as to show that he feels them. The great rule here is to follow nature, and to consider how she teaches us to utter any sentiment or feeling of the heart. Gesture, or action, as it is frequently termed, is of great importance to the orator. "Action," says Cicero, "which, by its own powers, displays the movements of the soul, affects all mankind," and "the countenance is next in power to the voice, and is influenced by the motion of the eyes. The great rule here, as in the previous case, is to attend to the looks and gestures in which earnestness, indignation, compassion, or any other emotion, discovers itself to most advantage in the common intercourse of men, and to take these for our models. For farther information on this subject, we may refer to the Institutions of Quintilian, who, in the last chapter of the eleventh book, has given many particular rules concerning gesticulation, which modern writers have done little else than translate.

DEFRINCLASSICS, del'-fin, in Lit., is the name given to an edition of the Greek and Roman classics, prepared and commented upon by thirty-nine of the best scholars of the day, under the editorship of Bosauct and Huct, at the instigation of Lonis XIV., for the benefit of his son the dauphin (in usum Delphin); whence their name. Many of the particular works have been reprinted in this country, and are well known.

DELPHINIUM, del-fin'-e-um, in Bot., a gen. of plants belonging to the nat. ord. Rannaculacea. The seeds of D. staphysagria, commonly called staves-acre seeds, have been used for destroying vermin. They contain an alkaloid called delphinia, which is occasionally employed medicinally as an external remedy in rheumatism and neursigia.

DELPHINUS, del-fil-nus (Lat. delphinus, the dolphin), one of the original constellations made by Aratus, an old Greek astronomer. It is close to the constellation Aquila. Its brightest star is one between the third and fourth magnitude, and it has four of the fourth magnitude.

DRITA, del'-tá, the Greek letter A.—The lower portion of Egypt, between the eastern and western branches of the Nile and the sea, was, from its resemblance to the letter above, called the Delta. In modern times, whenever a river, before entering the sea, diverges so as to form a triangle, with the sea-line for the base, the alluvial deposit included by the three lines is called a delta. The existence of a delta at the mouth of a river depends not so much on the amount of sediment held in suspension as on the presence or

# Deluge

absence of currents met with at the point of discharge. Deltas are not to be found where there are strong ebb tides; in such case deposit is washed away. But in sheltered bays and gulfs, in the Mediterranean Sea, where there are scarcely any tides, and in inland lakes, deltas slinost invariably occur.

deltas almost invariably occur.

Detroop, del'-toid (Gr. A delta), in Anat., is a muscle of the shoulder, which moves the arm either forward, backward, or upward. It is so called from its resemblance to the Greek letter delta. In Bot., the term deltoid is applied to a leaf of triangular form.

DELUGE, dell'suje (Lut. diluoium), is either a partial or general overflow of water, flooding the land. It is generally applied to that great overflow of water narrated in Scripture, and commonly known as the Flood. This great event is ordinarily calculated to have occurred in the 1656th year after the Creation, and 2293 years before Christ. We are told in Genesis (vii.) that all before Christ. We are told in Genesis (vii.) that all the fountains of the great deep were broken up, and the windows of heaven were opened, and God caused it to rain forty days and forty nights upon the earth; that during that time the waters increased and pr vailed exceedingly upon the earth, and all the high hills and mountains were covered fifteen cubits and up-wards; that all flesh died that moved upon the earth, wards; that an less due that moved upon the sard, and every man save Noah and those that were with him in the ark; that the waters prevailed upon the earth an hundred and fifty days, and at the end of that time they were shated, God having made a wind to pass ever the earth and assuage the waters; the fountains also of the deep and the windows of heaven being stopped, and the rain from heaven restrained. Noah entered the ark on the 17th day of the second month; on the 17th day of the seventh month the ark rested upon the mountains of Ararat, and on the 1st day of the first month of the year following, the waters were dried up from the carth, and about two months later the earth itself was dried. Such is the concise account of this great catastrophe given in sacred writ, a subject which has given rise to much discussion, and furnished materials for the cavillers at religion. Without going into all the points connected with this subject, we may briefly allude to a few of them. the legends and traditions of most of the earlier races upon the earth (the Chinese, Hindoos, Persians, Greeks, &c.) accounts of a similar catastrophe, and though sometimes they are in an allegorical form, yet they so closely resemble the account given by Moses, that they have generally been regarded as referring to the same event. Even the Mexicans, Peruvians, and other ruder nations of the new world, are represented as baving their traditions of the great deluge. rous ingenious and fanciful theories were formerly given forth in order to explain the phenomena of the Deluge; and early geologists believed that they found in the fossil remains imbedded in the earth unquestioned evidence of this universal destruction. So far was this the case, that infidel writers found themselves reduced to the absurd shift of representing them as lumin nature. So far as the testimony of geology goes, we have no evidence that bears directly upon this subject. Some of the ablest geologists are of opinion that the Deluge as described by Moses had been so gradual and of so short duration that it could have produal and of so short duration that it could have produced comparatively little change upon the surface of the earth. "The simple narrative of Moses," says the late Dr. Fleming, of Edinburgh, "permits me to believe that the waters rose upon the earth by degrees; that means were employed by the author of the calmity to preserve pairs of the land animals; that the flood exhibited no violent impetnosity, displacing neither the soil nor the vegetable tribes which it supported, nor rendering the ground unfit for the cultivation of the vine. With this conviction in my mind, am not prepared to witness in nature any remaining am not prepared to witness in nature any remaining marks of the catastrophe; and I find my respect for the authority of revelation heightened when I see on the present surface no memorials of the event." The majority of the ablest scientific men and theologians are now, however, of opinion that the Flood was enly partial, and not universal. It was sent as a judgment of God against impious men, and there is no reason to believe that the human race had then spread themselves over the entire surface of the globe. The word all, in accordance with Eastern phraseology, is not always in

Demi

Scripture to be taken in a strictly literal sense; and hence, in the Mosale account, there is nothing that can be regarded as contrary to the view of the Delugo being only partial. The object to be effected was the destruction of ungodly men, and if there be no reason to conclude that they were at that early period extensively scattered abroad, we think there is abundant evidence to abow that God is always very economical of his means, and never has recourse to great measures in order to effect what may be brought about by small. The opinion of a partial deluge has been taken up and developed by Hugh Miller in his last great work, the "Testimony of the Rocks." "There is," he says, "a subject to the state of the says, "a subject to the "There is," he says, "a remarkable portion of the globe, chiefly in the Asiatic continent, though it extends into Europe, and which is nearly equal to all Europe in area, whose rivers (some of them, such as the Volga, the Ural, the Sihon, the Koor, and the Amoo, are of great size) do not fall into the cosan, or into any of the many seas which surround it," but lose themselves in the eastern part of the tract in the lakes of a rainless district, and in the western fall into seas such as the Caspian and the Aral. In this region there are extensive districts still under the level of the ocean. "Let us suppose," he continues. "the human family still amounting to sevewars and exhausting view, were congregated in that tract of country which, extending eastward from the modern Aranat to far beyond the See of Aral, includes the original Caucasian centre of the race. Let us suppose that the hour of judgment having at length arrived, the land began gradually to sink, as the tract in the Run of Cutch sank in the year 1819, or as the tract in the southern part of North America, known as the Sunk Country, sank in the year 1821. Further let us suppose that the depression took place slowly and equally for forty days together, at the rate of about four hundred feet per day, a rate not twice greater. the original Caucasian centre of the race. four hundred feet per day, a rate not twice greater than that at which the tide rises in the Straits of Ma-gellan, and which would have rendered itself apparent as a persistent inward flowing of the sea. Let us further suppose that from mayhap some volcanic outburst coincident with the depression, and an effect of the same deep-seated cause, the atmosphere was so affected that heavy drenching rains continued to descend during the whole time, and that though they could contribute but little to the actual volume of the flood, at most only some five or six inches per day, causes, and added greatly to its terrors, by swelling the rivers and rushing downward in torrents from the Euxine Sea and the Persian Gulf on the one hand, and to the Gulf of Finland on the other, would open up, by three separate channels, the fountains of the great deep, and which included, let us suppose, an area of about 2,000 square miles each way, would at the end of the fortieth day be sunk in its centre to the depth of 16,000 feet, a depth sufficiently profound to bury a gradient of declination of but sixteen feet per mile, the contour of its hills and plains would remain appa-rently what they had been before. The doomed inha-bitants would see but the water rising along the mountein sides and one refuge after another swept away, peared; and when, after 150 days had come and gone, the depressed hollow would have begun slowly to rise, and when, after the fifth month had passed, the ark would have grounded on the summit of Mount Ararat, all that could have been seen from the upper window that could have been seen from the upper window and mould be simply a boundless see, rough cared; and when, after 150 days had come and gone, of the vessel would be simply a boundless sea, roughand the vesses would be simply a boundless sea, rough-ened by tides now flowing outward with a reversed course toward the distant ocean by the three great outlets, which, during the period of depression, had given access to the waters. Noah would of course see that the fountains of the deep were storned and the that the fountains of the deep were stopped, and that the waters returned from off the earth continually; but

its original and proper signification; but it came afterwards to be applied in a bad sense to such as attempted wards to be applied in a bad sense to such as attempted to mislead the people, and gain them over to their own selfish views, and who did not hesitate to resert to deceit and falsehood for that purpose. In its original acceptation it was regarded as a most honourable designation, having been applied to Solon, Demosthenes, and others of the most illustrious men of antiquity; but it is now almost invariably used in a bad

production on the part of the buyers, in order to enable them to purchase what they are anxious to obtain. Hence a universal increase of production leads to a corresponding increase of consumption. The relations between the demand for an article and its supply determine its price, which will rarely vary, for any length of time, much above or below its cost of production. Though the first effect of a demand exceeding the supply of a commodity is to raise its price, yet the in-creased price attracts the competition of others, and fresh labour and capital are employed in its production, until the supply is accommodated to the demand or exceeds it. In some cases, however, where the supply is necessarily limited, the price rises in proportion to the deficiency, and the number of consumers is diminished. Where, as in articles of food, the demand is universal, the effect of a deficiency is to raise the price higher and higher until a fresh supply can be obtained. The general effect of lowering the price of an article is to increase the amount of consumption, and of raising the price to diminish it. supply of any article exceeds the demand, the reverse of all this takes place, and the prices generally fall in proportion to the excess of the quantity. An excessive production of any commodity is always attended with evil to the producers, who aust either cease to produce or must produce in less quantities: and not only does it act injuriously upon them, but extends also to other classes, inasmuch as the consumption of these producers is diminished. "In proportion to the extent of the is diministed. In proportion to the extent of the market, and the variety and abundance of commodities to be exchanged, will be the facility of disposing of the products of capital and labour; and this consideration points out as the most probable autidote to gluts, a universal freedom of commerce. When the free interchange of commodities is restricted, not only is a glut caused more easily, but its causes are more uncertain. and dependent upon unforescen events. With the whole world for a market, the operation of the laws of demand and supply would be more equable, and the universality of the objects of exchange would make gluts of rare occurrence."—English Cyclopædiu, sect.

gluts of rare occurrence. — any many facts and Sciences.

Demarcation, Line of, de-mar-kai'-shun (Fr.), in the language of politics, is applied to the line or boundary agreed on by two contending parties, or fixed by a third, regarding some disputed territory. The term originated in the 15th century, when Pope Alexander VI., in order to settle the disputes of Spain and Portnaul on the subject of their Indian possessions.

and Portugal on the subject of their Indian possessions, drew an imaginary line through the ocean, defining the possessions of both parties, and to this line the term demarcation was first applied. It has now come to be used in this sense in most of the languages of Europe, DEMESKE, de-mech' (Nor. demainer, demayne, probably from Lat. dominium), such lands as were next to the lord's mansion, which he retained in his own hands for the use of his household and for hospitality. At the wreaper day. demans signifies the right which the waters returned from off the earth continually, but whether the deluge had been partial or universal he could neither see nor know."

Demagogus, leader), was applied, in ancient Greece, to such persons as by their abilities had great power in gaining over the mass of the people to their views, and thus obtained great influence in the state. This was applied, in ancient Greece, to gaining over the mass of the people to their views, and thus obtained great influence in the state. This was applied, in an of requently used in

the composition of English words; as demigod, helf-god.

Bangon.

Danzgons, dem'-e-gods, in Greek and Roman Myth., were a kind of half-gods, an inferior kind of deities, who were regarded as having something earthly in their composition. They were generally the spirits of such men as had been deified, more particularly such of them as were regarded as the offspring of divinities and mortals.

DEMI-HAQUE, dem'-e-hak (Fr.), the name of a small firearm in general use about the end of the 15th century. It was like a large pistol in form; but the butt was long and greatly curved. It was, as the name implies, a diminutive of the haquebut, or hook-butt, a musket the stock of which was curved, instead of being straight like that of the arquebus or hand-gun, the shape of which prevented these weapons from being held in a position which would allow the eye to be

the snape of which present these waspons roll being held in a position which would allow the eye to be directed along the barrel towards the object aimed at.

DEMI-IUMA, dem'-e-lune (Fr. demi, half; lune, the mion), in Mil., the name sometimes given to the ravelin, a work erected beyond the main ditch, in front of the curtain, to defend this part of the fortification and the flanks and shoulders of the collateral bastions. It is composed of two faces, forming a salient angle towards the open country, and is surrounded by a ditch communicating with the main ditch. It is open towards

the rear, and gained by a caponnière thrown up across the ditch in a line perpendicular to the curtain.

Draise, de-mize' (Fr. démise), a term applied to the conveyance of an estate, either in fec, or for life, or years. The king's death is, in haw, called the demise of the king to his royal successor. In England, according to public law, "the king never dies;" for immediately the death of the reigning monarch occurs, the Sovereignty passes to his successor; no ceremony or instal-lation is required, the successor becoming monarch by the act of the law itself. Blackstone thus writes of this custom:—"So tender is the law of supposing even a possibility of his death, that his natural dissolution is generally called his demise, an expression which

is generally cancer in termise, an expression when signifies merely a transfer of property."

DEMIURGE, dem'-e-urj (Gr. demiourgos, from demos, people, and ergon, work), is literally a workman or handicraftsman, and was employed by the Gnostics to denote a being whom they regarded as the creator of the visible world. He was, in their view, the archon or chief of the lowest order of the spirits in existence prior to the creation of this world; and it was he, they

prior to the creation of this world; and it was he, they said, that, by contact with chaos, gave to this earth its form and living characters. From him man received his psyche, or sensuous soul; while from God, the supreme divinity, he received his higher spirit, or pneuma. In this way they attempted to account for the existence of a good and evil principle in man, and for the origin of evil in the world. (See Gnostics.)

DEMOGRACY, de-mok'-rö-se (Gr. demos, and kratee, 1 rule or govern), is usually defined to be a government in which the whole of the people, or a great proportion of them, exercise the sovereign power, either directly or by means of representatives. Among the Greeks, from whom we have received the term, it denoted a government in which the svereignty was exercised by the great body of the citizens. It was also necessary to a democracy that the majority of the also necessary to a democracy that the majority of the citizens be of the poorer class; for, according to Arissotle, if a considerable majority of the citizens are rich, and exclude the remaining body, who are poor, from political rights, this is not a democracy. A pure political rights, this is not a democracy. A pure democracy is when every adult male citizen of sound mind has an equal share in the sovereign power. Such a condition could only exist in very small communities, as were the states of ancient Greece; and in modern times we have examples of it in some of the Swiss can times we have examples of it in some of the bwise can-tons, where all public business is discussed in a full assembly of the people. It thus became necessary to have recourse to delegates or representatives, elected by the people for the purpose of carrying on the government, and invested with powers for that purpose. So long as these are held responsible to the sovereign Bo long as these are not responsible to the sovereign body by whom these powers are delegated, this is still a democracy, though it is awdently less pure than the other, as the will of the people is only indirectly exer-dised, and is hence liable to be misrepresented or trossed. Even if the sovereign power should only be

in the hands of those who were possessed of a certain amount of property, if these should constitute the great majority of the people, this would still be called a democracy. The best form of government for any particular state is that which is best suited to its condition. dition. In some cases a monarchy, in others an olidition. In some cases a monarchy, in others an objectory, and in others a democracy, may be the best; but the ideally perfect form of government,—that which is best adapted for a people in its highest state of development, is the democratical, eating in its most practicable form, i.e. by representatives. We believe that not only does it produce the best form of government, and establishes it upon a firm basis, but that it also acts most hearticially in devaloning the intellectual ment, and establishes it upon a firm basis, but that it also acts most beneficially in developing the intellectual and moral qualities of the people. Hence the importance of a gradual and steady extension of the rights of government till they reach all classes of the people. The principle of democracy is that of equality, and of every member of a community being emittled to svoice in the affairs of that government of which he is a subject. In order to this however, it is necessary that in the anairs of that government of which he is a sub-ject. In order to this, however, it is necessary that he give satisfactory evidence that he is possessed of a sufficient degree of intelligence and integrity to exer-cise this power aright, and not use it merely for the furtherance of private or party ends. In a well-formed democracy, each one ought to see clearly what the true interests of the state are, and seek to advance them, So low as one clear or narty fancies that it is few the So long as one class or party fancies that it is for the interest of the state that another class or party be kept in check, and if one of these parties must have the rule, history has always shown that it is best in the hands of the anistocracy. It may be, however, that the party feeling is so strong, and their power so equally balanced, that neither of them can obtain the rule, or neither of them may possess the ability, though they had the power; then an intelligent monarchy, even though it may be an absolute one, is undoubtedly the best for that people.

Drmon, de'-mon (Gr. daimon), was the name given

by the ancients to certain spirits or genii, which they regarded as intermediate between gods and men. According to Plato, the name is derived from daemon, knowing, in allusion to their superior intelligence. Homer and some of the earlier of the Greek writers applied the term generally to every order of being superior to man; hence the gods were sometimes called demons, and the adjective daimoniakos was used to signify divine. In Hesicol we have an express account of the demons, as spirits intermediate between gods and men, being the souls of men who had lived in the golden and silver ages, and of whom there were different orders. According to Plato, the demon is a middle intelligence between the gods and men, watching over, directing, and recording the actions of the latter. In the opinion of some, the celestial deities did not at all interfere in the management of human sffairs, but committed it entirely to the care of the demons; and that every mortal at birth received a particular demon, who accompanied him through life and acted as his guiding spirit. According to their influence, demons guiding spirit. According to their innumes, demons were distinguished as good and bad,—agathodemons and cacodemons (Gr. agathos, good, and kakos, bad); but in either case they were regarded as carrying out the intentions of the gods, and not as being in any degree hostile or opposed to them. Hence, in its original sense, a demon was not necessarily an evil spirit, an idea which has come to us from the Jews, who were wont to regard the deities of other nations as only embodiments or emissaries of the Evil One. The genii of the Romans were analogous to the demons of the Greeks, though they differed from them in many important particulars. Every individual was believed at birth to receive a particular genius, which accompanied him through life, and conducted him through its various vicasitudes. The genius was rethrough its various vicissitudes. The genius was re-presented as enjoying the good things of this life; and hence for one to pinch his appetites was to defraud his genius. It was generally believed that each person genius. It was generally believed that each person had two genii,—a good and a bad; and as the one or the other prevailed, so was his conduct good or the reverse. Places and cities, as well as men, were believed to have their particular genii. The origin of the doctrine of demons is to be sought in the Rest. The Hindoos associated with their supreme deity, Brahms, an innumerable host of messengers or demons,

# Demoniacal Possession

called deitjus; and the Persians still further developed and systematized this doctrine of subordinate spirits. In accordance with the dualistic principle of their religion, they had two kinds of dentons—those who were servants of the good principle, or Ormusd, and were called Izeds, or genii of the Light, and those who served the evil principle, Ahriman, and were called the Dews, or genii of Darkness. The Jews, at the time of the Babylouish captivity, doubtless became acquainted with the system of the Persians; and to this may perhaps be attributed many of the popular notions that were afterwards held by them on this subject. Among Christian writers demons are simply fallen ancels, or doubt a contract of the contract and systematized this doctrine of subordinate spirits. subject. Among Christian writers demons are simply fallen angels, or devils, as used in the New Testament; and demonology is thus a discourse on the supposed nature and properties of such evil spirits, and of the superstitions regarding them. (See MAGIC,

WINCHCHAFT.) DEMONIACAL POSSESSION, de-mon-i'-a-kal, is one of these questions that has occasioned a great deal of discussion, and which, to Christians, has presented no fow difficulties. We do not indeed sympathize much with those who would bring everything to the touchwat those who would bring everything to the touch-stone of their own imperfect reason, and who cannot be made to believe in anything that is not perceptible to the senses; yet there are difficulties connected with this question that necessarily keep one from speaking with any degree of certainty regarding it. The question is, whether, when Christ was upon the earth, wicked and impure spirits were permitted to take up their abode in the bodies of human beings, directing, con-trolling, and tormorting them. Those who hold that trolling, and tormenting them. Those who hold that this was not the case, maintain that the appearances which characterized those said to be possessed, do not differ in any particular from what we observe in certain diseases in the present day; that such beliefs were common to the age and people among whom Christ was; and that he, when speaking of demons, merely conformed his language to their understandings, and spoke so as to be understood by them. On the other hand, it is a supple of the conformed his language to their understandings, and spoke so as to be understood by them. On the other hand, it is the conformed his language to the conformed his language to their numbers. it is argued that the appearances were such as showed that the demoniacs were not mere lunatics, or epilep-tics; that they knew Christ, and acknowledged him to be the Holy One of God; that Christ himself addressed them as unclean spirits; and that the account of the demonsentering the herd of swine cannot be accounted for in any other way. The question is beset with diffi-culties; but we do not think it a conclusive argument against demoniacal possession, that because we have no evidence of it in the present day, therefore it could not base existed at any previous time, or under any other circumstances. We are sufficiently ignorant of the apprit world that we may well speak with caution as to its nature and powers. There are numerous still units nature and powers. There are numerous still un-solved questions relative to the connection that subsists between mind and matter; we see, even in recent times. old forms of disease disappearing, and new and pre-viously unknown diseases taking their place; and lastly, the doctrine of demoniacal possession is con-sistent with the whole tenor of the sacred Scriptures. People would do well to bear in mind the inscription on La Motte's sundial, when attempting to speak authoritatively on such subjects,—" Quand je ne vois pas clair, je metais," When I do not see clearly, I am silent. In je metais," When I do not see clearly, I am silent. In

the early ages of the Church there was a peculiar service appointed for the cure of demoniaca.—Ref. Farmer's Essay on Demoniacs; Moses Stuart's Sketches of Angelology, in Bibliotheca Sacra, 1843.
DEMONSTRATION, demonstrati-sham (Lat. demonstro, I show or point out), was used by the old English writers to denote any manner of showing either the connection of a conclusion with its premises, or of a phenomenon and its asserted cause; but in philosophical knowners it now only means that process by which is mannars in the work of the contraction of a conclusion with its process by the contraction of a conclusion with the process by the contraction of the c phical language it now only means that process by which a result is shown to be a necessary consequence of the premises from which it is asserted to follow, these premises being admitted either as matter of fact, of intuitive evidence, or of previous demonstration.
In ordinary language the term is often used as synonymous with proof. Demonstration is either direct indirect: it is direct when the truth of the proposition matter: It is affect when the trius of the proposition is proved at once and directly, and indirect when it is proved by showing that the contradiction is impossible and about, which is usually termed reductio ad absender. Ref. English Cyclopadia.

#### Dandrolites

DEMONSTRATION, in Mil., the name given to a die play of troops in any particular direction, the object of which is to lead the enemy to imagine that some attack which is to lead the enemy so imagine that some attack or movement of importance is meditated in that quar-ter, and induce the officer commanding to detach a force to watch the troops so employed,—a measure which will tend to weaken his means of deteace at that point against which any attack or managuers is really directed.

or EUOHORIAL CHARACTERS, de-mot ik DEMOTIC Gr. demotikes, of the people), are terms applied by antiquaries to a certain kind of writing practised by the ancient Egyptians, and formed out of the ancient hieroglyphic, being a kind of current hand employed. by the people generally, and differing from the hieratic, or that used by the priests. It is sometimes found on public monuments along with the ordinary hieroglyphic writing, as on the famous Rosetta stone.—(See Hizzo-GLYPHICS.)

DEMULCENTS, de-mul'-sents (Lat. demulceo, I soften). is a name given to such medicines as are especially useful in obviating the action of acrid and stimulating matters, and that not so much by correcting or changing their nature as by involving them in a mild and viscid fluid, which prevents their acting, or by covering the surface exposed to their influence. They are genenerally divided into two classes, mucilages and expressed oils. In the former are almonds, collision, Arabic and several other gums, linseeds, mallows, liquorice-root, barley, cats, wheat, sago, and starch; in the latter, most Kuropean and unny foreign oils, fat, and other animal substances, including hartshorn-shavings, gelatine and isinglass, spermaceti, and wax. They are principally used in catarrh, diarrhoes, dysoutery, gravel, and a few other complaints.

DEMURRAGE, de-mur'-raj (from Fr. demeurer, to detain), in mercantile affairs, denotes the detention of a ship by a merchant, in loading or unloading, beyond the time specified in the charter-party, or other agreement with the owners. It is usually or other agreement with the owners. It is usually stipulated in charter-parties that the freighter may detain the vessel for a specified time, or as long as he pleases after the time specified for loading or unloading, on paying so much per day for overtime. During the receiving or discharging of the cargo, the merchant is liable for all detention from ordinary causes, even though these be inevitable or beyond his control; while the shipowners have the risk of all interruptions from the moment the loading or unloading is completed.

DENARIUS, de-nai-re-us (Lat. deni, ten each), was the name of the principal silver coin among the Romans, and was at first equal to ten asses, but afterwards, when the as was reduced, the denarius reprewartes, when the series are the series and the series are series are the series are the series and right under the Empire. The Romans had also a gold denarius (aureus devarius), equal to ten silver denarii; and also a copper denarius (denarius aris or areus), of which there were six in a silver denarius. The denarius has usually s belmeted figure of Rome on the one side, and chariots drawn by two or four horses on the other.

chariots drawn by two or four horses on the other.

DENDROLEGUS, den-drol'-e-que (Gr. dendron, tree; lego, I choose), a gen. of Marsupialian animals belonging to the Kangaroo fam. They, however, differ considerably from the rest by their adaptation to an arboreal life. The size of the animals belonging to this family differs considerably, some of them measuring more than four fect in length, independent of the sweeping tail; while others (see Kangaroo Rar) are no larger than a small rabbit. The tree kangaroes are found rather plentifully in New Guinea. New Guinea

DENDROLITES, den'-dro-lites (Gr. dendron, tree; lith stone), the petrified stems of trees and plants found in the secondary formations, and especially in the coal strata. These remains are found in very different sizes. strats. These remains are found in very different sizes, some being gigantic. Sometimes they are found with fossil branches, fruit, and even leaves; but in general, they are only found in fragments. The wood from which dendrolites originally were formed, mostly belongs to the Filices, the Cycades, and the Coniferency and it is generally converted into agate or pitch-stone. There is considerable doubt as to their crigin, and some of them are so hard that they are cut and used for

## Dendrosaura

artistic purposes. When cut into very thin plates, and examined purposes. When our into very tim pisses, and examined under the microscope, they show the structure of the wood perfectly, and it is possible for the boxanist not only to name the order or family, but to specify the genus and species of plants to which it belongs. Brongniart was one of the first who devoted himself to the study of this brongh of calendary. himself to the study of this branch of science.

DENDROSAURA, or TREE-LIZARDS, den-dro-saw'-ra' (Gr. dendron, tree; sauros, lizard), the term applied to a gent of reptiles of which the chameleon may be

regarded as the type. Dangue, or BREAK-BONE FEVER, deng(r), is the name of a disease that has, on several occasions, re-cently made its appearance in the southern states of North America and the East and West Judies, and is characterized as a severe inflammatory fever, accom-Danied with rheumatic pains in the joints and muscles. Though very severe, it is not often fatal, and usually terminates in a few days with a copious discharge of perspiration.

DENIZATION. den-e-zai'-shun, the act of enfran-chising or making free an alien born. (See next art.) DENIZER, den'i-zen (Welch dinassdyn, man of the city), is applied to one who is by birth an alien, but the has been made an English subject by letters atout or by certificate of the home secretary of state.

Though he enjoys more privileges than an alien, he is not on an equal footing with a natural-born subject. He cannot hold any office of trust or receive a grant of lands from the crown. He may hold lands by purchase, which an alien cannot, but he cannot take by inheritance, neither can his issue before denization inherit to him.

DENOMINATIONS, THE THERE, de-nom-e-nai'-shuns (from Lat. denomino, I name), a term applied to an association of dissenting ministers residing in and about London, organized in 1727, and which possesses the privilege of presenting addresses at court. three denominations are the Presbyterian, the Independent, and Baptist; and there are about a hundred and fifty members, of whom about one half are Independents. The origin and objects of this body are involved in some obscurity. They are very attentive to court etiquette, and present dutiful and loyal addresses to the sovereign on the occasion of births, marriages, deaths, &c. of members of the royal family. On presenting their address on the accession of a new sovereign, the whole body are introduced, and have the honour of kissing hands; on other occasions they pre-sent their addresses by deputation of about twenty, who are received in the royal closet.

DEROMINATOR, de-nom-e-nut-tor (from Lat. denomino, I name), the number of parts into which a unit is divided in any fraction. It is distinguished from the numerator, which specifies the number of parts of a certain kind which are to be taken; thus, in the frac-tion \$\frac{1}{2}\$, 3 is the numerator, and 4 is the denominator.

DENOUEMENT, da-noo'-mawn(g), (Fr. dénouer, tountie or solve), is usually employed to denote the termination or catastrophe of a play or story, but more strictly it denotes the train of circumstances that bring about the catastrophe.

DENS, deue, is the Latin term for a tooth, in the plural dentes; whence come such English words as dentist, dentition, dentifrice, &c.

DENSITY, deu'-si-te (Lat. densitas), a term which has

exactly the same practical meaning as specific gravity. If two substances are of equal bulk, but one contains more matter than the other, it is said to have more density. The quantity of matter is measured by the weight; and thus specific gravity and density become proportional. Rarity is opposed to density, and the sarest body known is hydrogen, and the densest body iridium, which is upwards of forty times the weight of water.

DENTIFEICE, den'-te-frees (Fr.), a substance, usually in the form of a powder, used as an aid in cleaning the teeth. Camphorated chalk is one of the most generally used dentifrices. Cuttle-fish shell and charcoal reduced to fine powder, are extremely useful as de-tergents. Pumice-stone is also employed when the teeth have become dark-coloured. Catechu, cinchons, and thetapy, are used in order to give astringency; myrth to give odour, and bole Armenian to impart colour to various tooth powders.

# Dechatruenta

DENTEROSTERS, den-te-ros'strees (Lat. dens. tooth; rostrum, beak), birds of predatory habits, and distinguished by the upper mandible being notched on either side. The butcher-bird belongs to this order. (See

BUTCHER-BIRD.)

DENTIST, den'-tist, is one whose business it is to treat diseases of the teeth. (See Treru and Topes.

ACHE.)

DENTITION, den-tish'-un (Lat. dentitio); is the breeding or cutting of the teeth, which takes place soon after-birth, and is frequently attended with various disorders. At birth the teeth consist only of pulpy radi-mentary substances, buried in the gum; and it is not till the third or fourth month after birth that they begin to assume shape and hardness. At this period children become uneasy and fretful; the gom is rod and swollen, accompanied with a feeling of itching, which is manifested by the eagerness with which they press any hard substance against the gums. The salivary glands sympathize with the guns, and there is a copious discharge of saliva. Frequently these symptoms of local irritation are accompanied by others of a more constitutional nature. The skin becomes dry and hot, the face flushed, the bowels relaxed, and the child very restless and fretful. A red rash usually also appears on the skin, called the red gum; and if the irritation extends to the muscles of the chest, there is a dry and troublesome cough. When the infant is in a tolerably healthy state, these symptoms usually subside in the course of two or three weeks; but if it be in a weakly condition, they frequently lead to serious and sometimes fatal results. The mucous membrane which lines the stomach and intestines may be affected from that of the mouth, and griping pains, nauses, vomiting, diarrhoes, and other disorders, may be the result. The external skin sympathizing with the internal covering may be affected with various kinds of eruptions; the air-passages and lungs may also become inflamed, or the brain and nervous system may become diseased, producing convulsions, epilepsy, tetama, &c.
The cutting of the teeth usually takes place between
the seventh and ninth month, though sometimes it is
much later. The gum again becomes extremely sensitive; but, instead of now being eased by the pres of a bard substance, it cannot endure the slightest touch. It is red and swollen, but paler at the upper part, which, just before the tooth appears, seems covered with a flat whitish blicter. The other symptoms are a repetition of those already described, with frequently eruptions about the head or lips, inflamms. tion about the ears, and occasionally spasmodic move-ments of the mouth and jaws. These diseases are not always confined to the period of infancy; for in irritable and nervous constitutions they sometimes manifest themselves (though usually in a less aggravated form) at the irruption of the second or permanent teeth, and even occasionally when the dentes sapienties are about to make their appearance. As the great exciting cause of these disorders is the local irritation in the gums, the great object to be kept in view in the treatment of them is to abate or remove this irritation. Where that is considerable, the gums ought to be freely lanced. As the flow of saliva and diarrhon are efforts of nature to carry off the inflammation, theseare not to be interfered with, unless the latter be excessive, in which case it is to be cautiously corrected by small doses of magnesia or carbonate of lime. Where the bowels are confined, small doses of cooling laxatives are to be administered. If there be drowsiness and oppressed respiration, irregular movements of the jaws, or convulsions, a leech or two to the temples, and a small blister to the back of the neck, or behind the ear, ought to be resorted to. Very mild opiates may sometimes be of benefit; but they ought only to be administered with the utmost caution, and never intrusted to the nurse. Extreme caution should also be exercised in meddling with any eruptions on the skin. Indeed, the period of dentition in children cannot be too scrupilously watched over; for there are few diseases that require more prompt treatment than some that then make their appearance; and, if not of themselves fatal, they often lead to serious or fatal disorders.

DEOBSTRUKETS, de-ob'-stru-ents (Lat. de, and ob-true, I obstruct), is a term applied to such medicines.

es have the property of pemoving obstructions in any part of the body, especially in the lymphatic system. They were formerly much used, and depended upon in medical practice; but latterly they have fallen into disuse. Almost the only deobstruents now employed are mercury, iodine, and bromine.

DEDDAMD, de'-o-dind (Lat. Deo dandam, given to God), was a term applied to a personal chattel which had occasioned the desth of a man without the default of sucother, and which was, by the law of England, forfested to the crown, in order to be applied to pious uses, or distributed as almo by the king's almoner. According to Blackstone, the custom was designed, in ording to Blackstone, the custom was designed, in the blind days of popery, as an expiation for the souls of such as were snatched away by sudden death; but it seems more probable that it is to be imputed to that natural horror which one feels at whatever has occasioned the death of a human being; or it may have been intended to teach caution to owners of cattle or implements which were attended with danger. The custom was also a part of the law of Moses; and similar regulations are to be found in the laws of most mations. Decodands were abolished in this country by \$\frac{3}{2}\$ \$\frac{1}{2}\$ \$\frac{1}{2}\$ \$\frac{1}{2}\$ to country by

DEONTOLOGY, de-on-tol'-o-je (Gr. deon, due, and logos, a discourse), properly signifies the science of duty, and expresses well what is commonly known as ethics, or moral science. It has, however, been adopted by moral science. It has, however, been adopted by Bentham and his followers to designate their own particular doctrine of ethics. "Deontology," says Bentham, "or that which is proper, has been chosen as a fitter term than any other which could be found to represent, in the field of morals, the principle of utilitarianism, or that which is useful."—Deontology; or, the Science of Morals.

DEPARTMENT, de-part'-ment (Fr. département), is a territorial division of France, which was introduced in 1790, at the instigation of Mirabeau. Previous to that time France was divided into provinces; but these were looked upon as too aristocratic by the revolutionists, and a new division was effected. The great object was to render them nearly equal to a certain average of size and population, so that the more populous departments are generally the smallest; but the rule was not uniformly adhered to. The names were chiefly taken from the rivers, mountains, or other prominent geographical features. The number of old provinces was thirty-four, and the number of departments formed was eighty-three. Afterwards, under Napoleon, the number was increased to one hundred and thirty; but till lately, the number has been eighty-six, when three new ones were formed out of the newly annexed territory of Savoy and Nice, making the number at present eighty-nine. Over each department is an officer called a prefect, appointed by the government, and a conseil de préfecture. The departments are subdivided into arrondissements, each of which is under a sub-prefect. Arrondissements are again sub-divided into cantons, and these into communes, cor-

responding in some measure to our purishes.

DEPUIGESTIGATED, de-flo-jis'-te-kai-ted, in Chern., a term used by the followers of the Stahlean theory to denute bodies which had been burnt or deprived of

their phlogiston. (See Phlogiston.)
DEFILATORY, de-pill-ö-to-re (Lat. de, from, and pilus, s hair), is a term applied to certain chemical substances employed for removing hair from the skin. Formerly employed for removing har from the same. For help it was usual to apply pitch to the part to be denuded, and shen to pull it forcibly away; but this rude practice is now discontinued. Most of the depilatories to be purchased, contain orpiment; and as this is an arsonical preparation, its employment is dangerous. One part of quicklime and two parts of carbonate of sorts, mixed and formed with water into a paste, and then applied to the part, will be found to be a good

depistory. de-ploy (Fr. deployer, to extend; Lat. de-plicars, to unfold), in Mil., when troops have been marching in column, and change the formation from column to line, they are said to deploy into line. In column, the front presented is narrow; but when the troops are in line, it is greatly extended; whence the

have a passive form, but an active or neuter significa-tion. They are so called because they have laid down,

as it were, the signification proper to their form.

DEFORMATION, de-por-tai-saus (Lat. deportatio), a kind of banishment in use among the Romans, in virtue of which a condemned person was cent to a foreign country, his estate confiscated, and himself deprived of the rights of a Roman citizen. During the French revolution, deportation was resorted to in hed of the revolution, deportation was resorved to in hea of the guillotine, and many political offenders were in this way got rid of. The punishment has lately been revived, and a number of troublesome persons have been removed to South America or Algeria. It ranks third in the order of punishments; capital punishment, and condemnation to the galleys or public works, for Hfe, below the trans below the property of the contract of the con being the two highest

DEPOSIT, de-poz'-it (Lut. depositum, from depono, I lay down), usually signifies a sum of money which one man puts into the hands of another as security for the fulfilment of an agreement, or as a part payment in advance. Among the Romans, a depositum was anything which one person put into the hands of another to be kept without any remuneration, and to be restored whenever demanded. The depositury was not bound to take more than ordinary care of the article, but he had to make good any loss occasioned by fraudu-lent design or gross neglect. To refuse to return a deposit involved infamy. The principles of the Roman law on this subject have been adopted by most modern nations.

DEPOSITION, dep-o-rish'-un (Lat. depositio), the testimony of a witness put down in writing by way of answer to interrogatories exhibited for that purpose in chancery, &c. Informations upon outh, and the evidence of witnesses before magistrates and coroners, are reduced into writing in the words used by the witnesses, or as nearly thereto as possible. Evidence in the court of Chancery is taken in written answers

to interrogatories, which are also in writing.

DEPOSITION, in the Church of Scotland, is the de-priving a clergyman of his ecclesiastical dignity and of the temporalities of his benefice, in consequence of immoral or seandalous conduct, or of holding doctrines contrary to the standards of the Church. Usually, proceedings are commenced in the presbytery within whose bounds the clergyman officiates; but an appeal lies against its judgment to the General Assembly. He may afterwards be restored by the General Assembly to his position as a minister, but he cannot be restored to his benealee.

DEFESTORED to INS DESIGNATE.

DEPOSITES, de-pos'-ifs, in Geol., those rocks which have been formed by the settling down of matter held in suspension in water. Deposits originate in denudation, the forming of alluvium, and the gradual collection of send, gravel, &c., at the mouths of rivers. (See DELTA.) Deposits are called marine, lacustrine, fluviatile, &c., according to the circumstances which attended their formation.

DRYOT, de-po' (Fr. dépôt), in Mil., the name given to any place in which naval and military stores are deposited, but it is more particularly applied to the town or barracks which form the head-quarters or home station of any regiment the main portion of which is serving abroad. Here the records and books of the regiment are kept, and one or two reserve com-panies are stationed, which are called depot companies. All recruits and young officers appointed to the regi-ment are sent to the depôt to be drilled, and to learn their duty before being sent out as reinforcements to the regiment wherever it may be stationed abroad. The depot system was introduced into the British service in 1825.

I) ETRIVATION, dept-ri-rait-shun (from Lat. de, and price, I take from, in Eccl. Law, is the removing a person from some degree, dignity, or order in the Church, and the depriving him of his ecclesissical preferments. The modes of deprivation are usually reduced to three heads:—1. Where the thing done is in itself actually null, void, and inoperative in iaw,—as the presentation of a layman to a benefice, and then there is no need of any sentence of deprivation. 2. Where the statute declares that upon the doing, or meaning of the term.

Deposites, de-po-nent (Lat. depone, I lay down), fineto deprived, there is no need of any sentence. 3.

It a term applied in Lat. Gram, to certain verbs which Where the doing, or the omission to do, certain acts

# Deputation

are causes only for deprivation by the ecclesiastic court, then there must be sentence of deprivation. I all causes of deprivation, where a person is in actual possession of a benefice, these things must occur: possession of a peneace, mess things must occur:—
2. The party must be cited and admonished to appear;
3. a charge must be given against him by way of libel or acticles; 3. a competent time must be assigned for his proofs and interrogatories; 4. the person accused shall have the liberty of coursel to defand his account. shall have the liberty of counsel to defend his cause to except against witnesses, and to bring legal proof against them; and 5. there must be a solemn sentence read by the bishop, after hearing the merits of the cause and the pleadings on both sides. Incontinence, drunkenness after admonition, and gross scandal, are deemed sufficient grounds for deprivation, when proved to the satisfaction of the court; also disobedience to the orders and constitutions of the Church; conviction of treason, murder, or other felony, by a temporal court; or of perjury, either in a temporal or ecclesiastical court.

DEFUTATION, dep-u-tai'-shun (Lat. deputatio), is a number of persons selected in order to represent the views of a larger body or company on any particular question, to lay their case before some person of in-fluence or in office, or to act for them in any particular affair.

DEPUTIES, CHAMBER OF, dep'-u-tees, was, under the French movarchy, the lower of the two legislative chambers in that country. It consisted of 430 members, representing the 86 departments, and holding office for three years. Each member was required to be at least 30 years of age, and to pay annually, of direct taxation, The right of election was vested in persons 25 years of age, and paying 200 francs of direct taxation; lists of such persons being made out annually by the mayors of the several communes, and revised by the mayors of the several communes, and revised by the prefect. The Chamber of Deputies was composed of three great divisions,—the côlé droit, côlé gauche, and the centres. The côlé droit, or right side, was to the right of the president's chair, and consisted of such members as were inclined to support the royal pre-rogative. The côté gauche, or left side, was occupied by those that usually supported popular measures; while those persons who generally supported the ministers occupied the centres (centre droit and centre gauche). The constitutional monarchy and representative government of France being overthrown by the revolution of 1848, a national assembly was instituted, the members of which were elected by ballot and a suffrage all but universal. The National Assembly was abolished in 1851, and the year following a new form of government was established. Corresponding to the Chamber of Deputies under the old régime, is now the Corps Ligislatif, or legislative body, composed of 261 members, in the proportion of one deputy to about every 35,000 electors in each of the departments. They every 35,000 electors in each of the departments. They are chosen for six years by universal suffrage, and each member receives an indemnity of 2,500 francs a month during the session. The emperor selects the president and vice-presidents from among the members, and has also the right of convoking, adjourning, or dissolving the body. The chamber has no power of originating any law, but merely of discussing and voting on such measures as are brought before it. If amendments are adouted, they must be sent to the Young on such measures as are orought before it. In amendments are adopted, they must be sent to the council of state, and no measure can be discussed that has not received the sanction of that body. The session lasts for three months, and, in case of a dissolution, a new one must be convoked within six months.

DEFOTY, dep'-u-te, is one who is appointed in the place of another, and who exercises the power that properly belongs to him. The appointment of a de-

properly belongs to him. The appointment of a deputy does not free the principal from responsibility.

DEER DAY, THS, day-be, the second day of the Epsom summer meeting, when the great race of the Derby stakes is run for. It is generally in the last week of May or the first week in June, and is always held on a Wednesday. The first Derby race was instituted by Lord Derby in 1780, and the stakes consist of fifty sovereigns each, with twenty-five torfeit. At the first Derby there were only 36 subscribers; but the race has ever since grown rapidly in fame and popularity; in this year (1862) the number of subscribers was 233; the number of horses starting 34, and the net was 233, the number of horses starting 34, and the net value of the stakes £6,525. The Derby day is the great 637

# Derrick

holiday for nearly all the inhabitants of London; the roads between the metropolis and Epsom are througed from an early hour with every variety of vehicle, and the railway frains are constantly leaving the stations, with fresh cargoes of passengers for the Downs. It is almost impossible to get a horse on the Perby daylin or about London. The horses that run in the Dechy must be three years old, and the course is a mile and half in length. An immense amount of money, heades that fin length. An immense amount of money, leaded the stakes, is won and lost annually on the result. The Derby of 1871 was won by Favonius, and was run in two minutes fifty seconds.

DEBENDED STAR, der be-sheer.—In Min., figor. spar is popularly known by this name, from the most celebrated fluor spar being found at the Blus John mine, in Derbyshire.

DEBELICT, der'-e-likt (Lat. de, and relinquo, I leave or forsake), in Law, is a term applied to such goods as are thrown away or relinquished by the owner. "Property both in land and movables being originally acquired by the first taker,—which amounts to a declaration that he intends to appropriate the thing to his own use,—it remains in him, by the principles of universal law, till such time as he does some other act which shows an intention to abandon it; for then it becomes, naturally speaking, public juris once more, and is liable to be again appropriated by the maxt occupant." In the case of lands gained from the sea, the law holds, that if this gain be by small and imperceptible degrees, it shall go to the owner of the land immediately behind; but if it be sudden and con-siderable, it belongs, by common law, to the crown; for the soil, when the sea flowed over it, was prima facie crown property, and therefore ought to remain so, though no longer covered by the sea. In the same way, in the case of an island rising in the sea, it is held to be the property of the crown, though the civil law gives it to the first occupant.—Ref. Stephen's Commentaries on the Laws of England.

DERIVATION, der-iv-ai'-shun (Lat. derivatio, from derivo, I drain off), in Med., is applied to the removing or drawing away of a disease from its original seat to another part by artificial means; as by the application of a blister in pleuritis. The doctrines held by the earlier physicians on this subject, as that the matter of the disease was thus drained away through some channel, are now quite exploded.

DERMATOLOGY, der-ma-tol'-o-je (Gr. derma, the skin, and logos, a discourse), is the science of the treatment of the skin and its diseases.

DERMESTIDE, der-mes'-ti-de (Gr. derma, skin; esthio, I cat), small beetles of a very destructive character. Nothing seems too tough for their digestion. Although obnoxious in many respects, the insects of this family are of infinite service in the economy of nature, by causing the rapid decomposition of animal matter into a substance fitted for the improvement of the soil, and by their labours, united with those of the Silpha, Necrophori, &c., destroying such portions of these remains as are left untouched by the flesh-flies, which only consume the soft portions of the carcuses."—
(Westwood.) The best known of the dermestes is D. cardurius, or bacon-beetle, a name applied through the insect's real or supposed fondness for bacon. It is the insect a real or supposed indimess for bacon. It is about a third of an inch in length, and of a dusky brown colour, with the upper half of the wing-shells ash-coloured, and marked with black spots.

DREMICK, derf-rik, a temporary crane, consisting

of a spar supported by stays and guys, carrying a pur chase for loading or unloading goods on shipboard. The derrick is an invention of Mr. Bishop, an American. Derricks have been used for a considerable time in America as lifting powers: they have been proved very expeditive and economical. One of the largest ever made was constructed by the Thames Iron Shipbuilding Company. It is a floating derrick, and consists of a flat-bottomed vessel 270 feet long and 90 feet across the beam. It is propelled by bucket pad-dle floats, and can be moved at the rate of four niles an hour. From the deck rises an iron triped 80 feet an hour. From the deck rises an iron triped 80 feet high, on the top of which a boom 120 feet long revolves. Above the boom is the king-post, a continuation of the tripod, 50 feet high. Ten fourfold blocks are attached to one arm of the boom, and the chains attached to

e are passed across the ki and of the boom, and down in the vessel, where they are connected with two powerful steam-engines. A body weighing 1,000 tens can dot only be lifted by this powerful crane, but can be transported from place to

Drawiss, der visk (Persian, a poor person), is em-ployed like the corresponding Arabic word Jakir, to denote a perticular class of persons in Moslem coun-tries, resembling in many respects the monks of Christendom. There are many different brotherhoods and orders of dervishes, who are generally named after iders of derrispes, who are governing to tradition, their originates from the earliest times of Islam, but they proble areas at a much later period. They mostly live bably arose at a much later period. They mostly live in richly-endowed convents called Tekkije or Changah, and are under a chief, who has the title of sheik or pir. i. c. elder. They are generally allowed to marry, pir, i. s. elder. They are generally another the but are obliged to sleep one or two nights a week in the convent of their order. Among some of the orders a part of their religious exercises consists in dancing and terring round with great velocity, while others and terring round with great velocity, while others and the seem generally to lead very worthless lives and to practise the grossest immoralities, yet they are regarded with great awe and veneration by

DESCANT, des-kant' (Sp. discante), a term formerly used to express the art of composing in parts. By Hubald, Odo, Guido, and others, it was employed to stenify concord and harmony of sounds. Descant is of three kinds; viz., Plain descant, which is synonymous with simple counterpoint; Figurative descant, which is less restrained, and includes the relief of discords; and Double descant, which denotes that arrangecords; and Double descant, which denotes that arrangement of the parts which will allow the treble or any high part to be converted into the bass, and rice verid. This term is also employed to imply a melodious display of notes extemporaneously played or sung to any given bass, as well as to denote the highest part in the score, viz., the soprano, or highest female voice.

DESCENT, de-sent' (Lat. descensus; Fr. discent, in which way the term is usually spelt in all old law-books), the title whereby a man, on the death of his ancestor, obtains the inhoritone as being-tallaw. The term in.

obtains the inheritance as heir-at-law. The term in heritance is sometimes used in the same sense, although it properly signifies that which is, or may be, inherited by descent. Descent is defined in the interpretation clause of the 3 & 4 Will. IV. c. 106, as "the title to in-herit lands by reason of consanguinity, as well when this heir shall be an ancestor or collateral relation, as where he shall be a child or other issue." Inheritances, hereditaments, things which may be taken by descent are various. The crown is the principal of these, the descent of which differs in one essential point from that of a private inheritance. When a king has no sons, the eldest daughter takes the whole of the inheritance, in exclusion of the younger sisters. Dignities and honours, such as baronies and other peerages, are descendible according to the limitations contained in the patents by which they were created. (See Hair, IMPRITANCE.)—Ref. English Cyclopædia, sect. Arts and Sciences, art. Descent.

and Sciences, art. Descent.

Description, des-krip-shun (Lat. descriptio, from de, and scribe, I write), in Literary Composition, is the placing of objects in a clear and proper light before the reader; a matter of so great difficulty, and requiring such high and varied powers, that many critics regard it as a test of genius. When we consider the great qualifiions that are necessary to excellence here, it is not to be wondered at that we find so few writers distinruished for great descriptive powers. "The best sessiners, says that, "are simple and concise. They set before usenoh features of an object as on the first view atrike and warm the fancy; they give us ideas which a statuary or a painter could lay hold of and work after them, which is one of the strongest and most declays tests of real merit of description." nous accuracy tests of real merit of description."
Objects ought to be painted so accurately as to form in
the mind distinct and lively images. Usaless circum-stances ought to be suppressed, because they load the examples ought to be apprecised, occase they lost the married or in numerous flocks, and a few monkeys and antelopes ever slight, it cannot be described too minutely. Inferior writers are continually striving to enliven their subject by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and a profuse use of supercular to the married by exaggeration and the m

latives, which unfortunately has the contrary effect to what is intended, and the reader is led by contrast to think more meanly of the subject than probably it deserves. A pradent man, in writing as in walking, husbands his strength, and reserves his strongest expressions for the most important points of his narrative. Reasons that are known to every one ought to be taken for granted; the expression of them is childish, and interrupts the progress—a uncertaint of world is interrupts the progress,—a superfinity of words is always a great nuisance in narration. Abstract or general terms are always to be avoided. Sometimes a single circumstance, happily introduced, has more power than the most laboured description. The words power than the most isbource description. The worths selected should correspond with the siless they are intended to convey,—an elevated subject requiring so elevated style, a familiar subject a plain style, and a serious subject as plain style, and a serious subject a verious style. A writer of genius is not apt to clothe a high subject in low words; but it is more common to find the expression raised above the more common to mid the expression raised above the tone of the subject. Description addressed to the imagination is susceptible of the highest ornaments that sounding words and figurative expression can bestow upon it. Writers of genius, sensitise that the eye is the best avenue to the heart, represent everything as passing in our sight, and from readers or hearers, transform us into spectators. "The force of language," says Lord Kames, "consists in raising complete images, which transport the reader as he language, says Lord names, consists in rasing complete images, which transport the reader, as by magic, into the place of the important action, and convert him into a spectator, beholding everything that passes. The marrative in an epic poem ought to rival a picture in the liveliness and accuracy of its representations: no circumstance must be omitted that tends to make a complete picture, because an imperfect image, as well as any other imperfect conception, is cold and uninteresting." There is no species of composition into which description does not enter in some chart, there are few compositions of any length that can be called purely descriptive. In descriptive poetry the highest exertions of genius may be displayed. "De-acription," says Blair, "is the great test of a poet's imagination;" and in the "selection of circumstances lies the great art of picturesque description." They ought not to be vulgar and common, such as are apt to be passed by without remark, but such as may eatch be passed by without remark, but such as may eaten the fancy and draw the attention. All the circum-stances employed ought to be uniform and of a piece, and ought to be such as particularize the object de-scribed and mark it strongly. "This happy talent," says Blair, "is chiefly owing to a strong imagination, which first receives a lively impression of the object, and then, by employing a proper selection of circumstances in describing it, transmits that impression in its full force to the imagination of others.

DESERT, dez'-ert (Lat. desertus, deserted, solitary), weste or large tract of barren country. The term is a weste or large tract of barren country. a weste of large tract of barren county. The term is applied very vaguely, but is more particularly appropriated to sandy and stony plains. According to Dr. Ami Boné, in a memoir communicated to the Association of German Naturalists at Gratz, in 1843, deserts, properly so called, always point out the site of a large gulf or inland sea. These large sheets of water bave now entirely disappeared, but they are of a compara-tively recent geological epoch. Deserts are distinnow entirely disappeared, but they are of a comparatively recent geological epoch. Deserts are distinguished by different names in various parts of the earth. The term desert is more particularly applied to the waste tracts of Africa and Arabia. Those in Asia, especially in Thibet and Tartary, are called steppes. In South America, the large plains, rank with vegetation but unfit for human settlements, are called llanos, pampas, and silvas, or desert-forests. The wide-stretching plains of North America are called prairies and savannahs. The desert of Sahara is the most famous of the properly accessed the stretches almost without properly so-called deserts. It stretches almost without a break from Cape Nun, on the north-west coast of Africa, castward to the banks of the Nile. In some parts of this desert, as at Tegazza, rock-salt as white as snow extends in vast beds beneath a stratum of rock. Rain only falls between July and October, and the vast plains are tenanted by lions, panthers, and serpents, often of a moustrous size. The ostrich is also found often of a monstrous size. The catrich is also found in numerous flocks, and a few monkeys and subleopes pick up a scanty silowance of food. Here and there, often at great distances, are a few small fertile spots,

chants, who travel on camels, hence called "the alips of the desert.

DESERTER, deserter (Let. deserces, to shandon), in Mar. and Mil., the name applied to any soldier or sailor who abscends from his ship or regiment for the purpose of avoiding the duties which he has consented to discharge for a certain period. Desertion is punished by imprisonment and diogning; but the number of lashes allowed to be awarded by court-martial is not to exceed fifty. It involves the loss of additional pay and penion, good-conduct movey and stripes, and rank as non-commissioned officer. If a soldier or sailor is merely absent without leave for a short period, the wreach of discipline committed sloes not amount to DESERTER, de-sert-ter (Lat. deservere, to abandon) merely absent without leave for a short period, the mered's of discipline committed sloes not amount to describe, and is punished by loss of pay for the time ne is absent, and confinement to barracks or extra drill. Any one who induces a soldier or sailor to desert is liable to penal servitude for life. The crime of desertion was formerly punished by death; and it is only since 1860 that the custom has been abandoned of branding the deserter on the breast or shoulder with the letter D.

DESERTION, de-zer'-hun, in Marriage.-Till recently the law of England made no provision for a wife's obtaining redress for wilful desertion by her husband; but by 20 & 21 Vict. c. 85, and 21 & 22 Vict. c. 108, desertion by either spouse is made a ground of judicial separation, and provision is made for the protection of property ecquired by a wife who has been deserted. In Scotland, one of the spouses wilfully deserting the other may first be sued for adherence, after one year; and, after four years from the time of desertion, may be divorced by the Court of Session.

DESICCATION, des-ik-kai'-shun (Lat. de, and sicco, I dry), in Chem.—Bodies are generally dried in-two ways, — by submitting them to heat, more or less gentle, or by inclosing them in a receiver, with concentrated oil of vitrol or chloride of calcium. The latter process is resorted to when heat would cause

the decomposition of the body acted upon.

DESIDERATUM, de-zid-e-rail-tam (Lat., wished for), denotes something that is wanted to the completness of a thing, or to promote the advancement of any

DESIGN, de-zine' (Lat. designo, I mark out), denotes. in a general sense, an intention, scheme, or plan of action, and in the Arts is applied to the idea or plan in the mind of the artist which he attempts to embody or represent in some visible form to the minds of or represent in some visible of the second of thers. Every work of design may be considered either in relation to the art that produced it or to the and that it is intended to serve. What is done with a end that it is intended to serve. What is done with a view to some effect that is to follow, is said to be the result of design; and from the adaptation of means to ends that we observe in nature, we are led to conclude that they are the work of an intelligent designer. For the arguments that are employed to prove the being of a God from the evidences of design that are to be seen in nature, see Paley's Natural Theology; the Bridgewater Treatises; and the Burnett Prize Essays.

DESIGN, in Arch., the name given to a set of geometrical drawings drawn to a certain scale, representing the different sides, interior, and extent, of any building, in such a manner that it can be erected by a builder in exact conformity with the original des or conception of the architect. When the building is small, these are taken as working drawings, but if it be of great size and extent, working drawings are made from them for the use of the builder on a larger scale. They are intended to show the proportions and outline of the required building, and in them the principles of perspective, and light and shade, are disregarded enperspective, and light and shade, are disregarized entirely as regards the former, and almost entirely with respect to the latter. The various parts of an architectural design for any building are respectively termed "plan," elevation," section," and "details." The plan shows the shape of the building and the area which it is to cover; it may be termed with propriety a horizontal section of the building; it shows the position of the walls of the rooms, and their rethe position of the wais of the rooms, and their re-spective thickness; the situation of rooms and pas-sages with regard to each other, and indicates the apertures required for doors, windows, fire-places, staircases, &c. The parts representing solid masonry-are coloured, while the open spaces are left plain, and 639.

indicated by dotted lines. A plan is given for a floor of a building, from the basement opwards the exterior of the roof is also represented in this the exterior of the roof is also represented in this man-ner. The elevations show the outline of the front, back, and sides of the building, and the windows, doors, projections of chimneys, and all the ornement-stion that may be introduced; such as string-courses, dressings of the doors and windows, cornices, anta-bletures, balconies, &c. The sections are represent-ations of the interior on a vertical plane, supposed to pass through the building from top to bottom, on any line indicated on the ground plan. They show the lickness of the floors, the height of rooms, the height and form of doors and fireplaces, the profiles of op-nicos, domes, and skylights, as well as that of the roof; the direction of staircases, &c. Details, or parts at large, are representations of the horizontal and ver-tical sections of different rooms and parts of the tical sections of different rooms and parts of the building on a larger scale than that which is used for the general plan: they are also drawings of any em-bellishment that may be introduced, and are neces-sary to make their intended form intelligible to the workmen

DESIGN, is an expression employed in the Fine Distor, is an expression employed in the Fine-Arts to signify the representation of any form of combination of objects, either in simple outline or in colour. It is applied indiscriminately to saything of this kind, from the sketch of any simple object or elementary form, that may be represented by a few strokes of the pencil, to the elaborate combinations required for the intricate pattern of a shawl or say other similar production of the loom, as well as to the composition of a picture, or group of figures, or the form of any work of art, whether useful or grammental. The most exquisite designs, with reference to attitude, elegance of form, and force of expression, are considered to exist in the works of the old Greak collators and the best Italian masters of the mediaval period such as the marbie: of the Parthenon, the cartoons of Raffaelle, and the statues of Michael Angelo; but there are modern painters who are in no way inferior to the old masters in design and power of conception; in proof of which may be mentioned Mr. Frith's wonderful painting known as "The Railway Station."

DESIGN, SCHOOLS OF.—The government echools of

design that are established in various parts of the scountry, in connection with the Central Training School at South Kenaington, which was originally opened at Somerset House in 1837, are intended to impart a knowledge of drawing and a taste for the fine arts to the great bulk of the people, and more par-ticularly to those who are employed as artisans and designers in manufacturing establishments of all kinds. It was the intention of the originators of the scheme to confine their operations entirely to the latter class; but it was soon discovered that the public generally would not appreciate beauty and symmetry of form and proportion, and harmony of colour, in objects of every-day use, before means had been taken to teach the people the general and rudimentary principles of the people the general and radimentary principles of art, and inspire them with a desire for that which is pleasing to the eye, whether in household furniture, paper-hangings, earthenware, or materials for the attire of the person, in preference to the ugly, un-shapely, and staring art-productions of the 18th and early part of the 19th century. It was also found, that however Englishmen might excel in the manufacture of everything in which strength and utility are required, they were far behind the French and other continental unitions in ornamental and decorative art, and did not apparently understand that stability and usefulness could be combined with elegance of form and pleasing colouring; and it was a knowledge of this, and an earnest desire to remedy this palpable deficiency in English art, that led the late Prince Consort to conceive and mature the idea of the Great Exhibition of 1851, to which the establishment of the schools of design may be considered, in some degree, to have been a stepping-stone. At all evants, the productions of British workmen in the International Exhibition of 1862 have shown that the leasons learns in these achools and the Exhibition of 1854 have and continental nations in ornamental and decorative art in these schools and the Exhibition of 1851 have not been lost; and the interiors of our dwellings show that our artisans are giving forms and ornament to the articles they produce, suitable to the purposes for

which they are intended wand that people are begin ning to see that it is more consonant with reason t and a secret figured with a geometrical pattern rather than gaudy bundles of flowers; and that the eye in better statisfied to rest on a jug of simple design and solour, whose outline is formed of graceful curves, tolon, whose outline is formed of graceful curves, than on one of that squat bulging form in blue and white, or two shades of brown, ornamented with uncouth figures in bas-relief, or the unmeaning willow pattern, which was the stereotyped fashion, both as regards shape and decoration, for jugs of all kinds some thirty or forty years since. The schools of design the under the control of the Science and Art Describes the Committee of Committee o partment of the Committee of Council on Education, and the offices of the department, and the Central Training School for the United Kingdom, are in Creawell Road, South Kensington. To this school both male and female students, that are duly qualified, are admitted, and partly maintained at the expense of the government while passing through the prescribed course of study. When they are fully competent, they receive certificates, and are sent as teachers to local schools in connection with the central establishment. Teachers in these local schools receive grants from government, in addition to their income, in proportion to the success of their pupils at the annual inspection and examination, when medals and prizes are awarded to the most deserving and efficient. A school of art may be founded in any locality in connection with the central school, provided that suitable premises can be obtained, at the public expense, the government, in some cases, bearing as much as one-fourth of the total cost when new buildings are erected for the purpose. It is also requisite that there be fire public schools for the poor, in which the master recommended by the department can give instruction, or 500 poor children in the district, who must be taught, if it be desired, free of expense. Pupil teachers in National and British schools are also entitled to receive instruction at a low charge; and an evening class must be held three times a week, at which any person can receive instruction in drawing for a sum not to exceed sixpence weekly. Successful students at the local schools send their drawings for competition to the central school, when queen's prizes and medals are the central school, when queen's prizes and medals are awarded to those who excel in any particular branch of art. Each school obtains drawings, works of art, or apparatus, to the amount of \$10, for every queen's prize or medal obtained by the pupils who have studied there. Every school of art may borrow books, drawings, and works of art from the museum and library at South Kensington; and any mechanics' or working man's institute can obtain assistance in the purchase of drawing models and casts for the purposes of instruction.

DESIRE, de-zire', is an affection of the mind excited by the view or the contemplation of any desirable good which is not in our possession, but which we are acti-citous to obtain. There is room for difference of opinion as to the number of our desires that are origuisd; but that certain of them are primarily inherent in our nature, scarcely admits of doubt. (See Ethics.) DESMODIUM, des-mo'-de-um (Gr. desmos, a bond, in al-

lusion to the stamens being joined), in Bot., a gen. of plants belonging to the nat. ord. Leguminosa. Some of this tropical species are remarkable for the periodical movements of their leaflets. In D. gyram, a native of India, the leaf is trifoliate, the terminal leaflet being much larger than the two lateral ones. When exposed to the influence of a bright light, the large leaflet besomes more or less horizontal; but, on the approach of evening, it falls downwards. The lateral leaflets are in constant motion during the heat of the day, are in constant motion during the heat of the day, indicateing by their edges towards the large terminal leader, and then retreating towards the base of the common petiole. This movement takes place first on one side and then on the other, so that the point of each leader describes a circle. As these movements resemble those of the arms of the old semaphore telegraphs, the plant has been named the telegraph-plant. We satisfactory explanation of the cause of the extraordinary movements of the leadets has yet been

ower is vested in the hands of one who is irresponsi ble or uncontrolled by others. The term is received from the Greeks, among whom it denoted that kind of relationship that subsists between a master and his claves. As a master had unlimited and uncontrolled power over his slaves, governing more by hardiness than concllistory measures, and viewing them only as intended to serve his own ends; so a despotic form of government was regarded as one where the sovereign government was regarded as one where the sovereign had unlimited power over the lives and fortunes of his subjects. But this idea of a despotism is one which could never have any existence in fact." No sovereign has ever been so absolute or despotic as that he gould carry out his wishes with a total disregard to every one elise. His power actually depends upon his having the support of a large body of his subjects; and its, is compelled to act so as to carry along with him their approval, or, at any rate, not to go in opposition to their wishes. The most absolute monarch that ever lived could not openly seize the property of a subject, or put him to death, without assigning some colourable grounds for so doing; for such an set would undoubt-edly endanger his crown. The existence of an absolute government, when carrying out oppressive measures, depends upon its being able to couceal or pervert the real facts of the case. Despotic rulers feel their dependence upon public opinion much more than those whose power is in some measure limited; and it is this that leads them to lay restrictions upon freedom of speech and of the press. According to some, a despotism may include any number of individuals governing for their own individual interests, to the exclusion of those of the whole community.

DESTINY, des'-time (Lat. destino, I fix or appoint), is an appointed or predetermined state or condition; the necessary and unalterable course of events predetermined by a superior Being. A belief in destiny or fats has been held by almost every people in every time, and has been usually incorporated in their religious beliefs. Among the ancients it was regarded as a power superior both to gods and men, governing all things irresistibly; for, according to Seneca, the Ruler of all things, in writing the book of destiny, prescribed the limits of his own power. According to the Stoics, destiny is a certain arrangement of events which follow ach other of absolute necessity, there being no power able to interrupt their connection; and hence every man ought with patience to submit to his fate, which no effort on his part could possibly avert. (See Fars.) The doctrine is also held by many persons in the Christian church. (See PREDENTINATION, FREE WILL.)

DESTRUCTIONISTS, des-truk shun-ists (from Lat. de-strue, I destroy), in Theol., is a name given to such as hold a kind of middle scheme between universal renoid a kind of middle scheme between universal restoration and cuidless perdition, or who maintain that the wicked shall neither be for ever miserable nor finally saved; but that, after undergoing an awful suffering proportioned to their crimes, they shall be utterly annihilated. This doctrine, they maintain, is implied in the scriptural word death, which they hold denotes a termination of miffering and the translation of miffering and the standard contract. implied in the scriptural word death, which they hold denotes a termination of suffering; and that eternal death is simply annihilation. Though there is apparently so little reason for this view, yet it has been entertained by some able theologians.

DESVAUXIACEE, dui-voze-e-ui'-se-e, in Bot., the Bris-DETACHMENT, and to ord. of monecotyledonous plants, in the sub-class Petaloidew. They are small, aedge-like herbs, with actaceous sheathing leaves. They are natives of Australia and the South-Sea Islands.

Detachment, de-ditch-ment (Fr. detacher, to unfasten), in Mil, the term applied to any body of troops, whether large are made of the same of the sam

resten), in mil., the term applied to any body of troops, whether large or small, sent from an army, division, brigade, regiment, or company, for the performance of some special service. Large detachments, consisting of cavalry, infantry, and artillery, almost forming a separate army, may be sent from the main body to create a diversion, and attract attention to some particular nearly that are the second particular ticular point; to carry on the siege of any fortress; to protect lines and bases of operation, or to act on those of the enemy; to prevent the junction of two separate detachments of the enemy; to capture or protect a convoy; or toget on the flanks or rear of an enemy on the field of battle.

DESPOTISM, des pot ism (Gr. despotes, master), in DESTRIGENTS, de ter jents (Lat. detergo, 1 wip. Pol., is a form of government in which the supreme away), is a name given to such medicines as cleans DETERGERTS, de-ter-jents (Lat. detergo, I wips

#### Determination

Development Theory

and remove viscid humours adhering to and obstruct ing the vessels; also such applications as cleanse foul

DETERMINATION, de-ter-min-at-shun (Lat.), in Med. is applied to the excessive flowing of the blood to any part; as a determination of blood to the head, &c.

DETINUE, det'-in-ue (Lat. detinendo), in Law, is the name of a writ which lies against one who, having goods

delivered to keep, refuses to restore them.

DETONATING POWDER, det'-o-nai-ting pow'-der (Lat. DEFORATING FOWDER, aer-o-mar-ting powr-der (Lat-detono, I thunder; Fr. poudre, p. powder), a term applied to certain combinations of substances which detonate or fulminate by slight friction, by heat, or by electricity. Amongst these may be mentioned the ammoniurets of gold and silver and the fulminates of silver and measure. and mercury. In most cases of detonating powders, decomposition is the result of detonation; thus, ammoniuret of gold is separated into metallic gold and other products. Iodide of nitrogen, a detonating powother produces. Induce of introgen, a deconsing pow-der, resolves itself into iodine, which appears as a violet vapour, and nitrogen, which assumes a gaseous form. A mixture of 3 parts of nitre, 2 of dry carbonate of potash, and 1 of sulphur, forms a detonating pow-der. If a small quantity of this compound be heated on a metallic plate to about 330°, it blackens, fuses, and explodes with much violence, in consequence of the rapid action of the sulphur upon the nitre, and the sudden evolution of nitrogen and carbonic acid. Detonating powders are much used in the manufacture of percussion-caps.

DEUS EX MACHINA, de'-us eks mai'-kin-ā (Lat., a god from the machine), is an expression borrowed from the ancient stage, it being usual among the ancient Greeks, when there was any difficulty in bringing the plot to a satisfactory conclusion, to have recourse to the assistance of a deity, who was let down in a machine for that purpose. In the modern drama, when a person or incident is arbitrarily introduced in order to bring about the dénouement, this is called a deus ex machina.

The rich old uncle who comes home unexpectedly from the West Indies, and rescues his scapegrace nephew from his pecuniary embarrassments, is a deity of this stamp. The expression is also by analogy sometimes madical text to rade in which come publishes these stamps. of this stamp. The expression is also by analogy some-times applied to the mode in which some philosophers attempt to account for facts which they cannot explain by any known law; viz., by the intervention of supernatural agency.

DEUTRIS agency.

DEUTRISO-CANONICAL, du'-te-ro (i.e., belonging to the second canon), a term applied by Roman Catholic writers to what is commonly termed by Protestants the Apocrypha, or the Apocryphal books of the Old Testament. They receive their name from their being regarded as inspired, but not of the same authority as

regarded as inspired, but not of the same authority as the canonical books proper.

DETTERONOMY, du-ter-on'-o-me (Gr. deuteros, second, and nomos, law), is the fifth book of the Old Testament and the last of what is termed the Pentateuch. This book was written by Moses shortly before his death, and embraces a period of five or six weeks of the fortieth year of the journeyings of the children of Israel in the wilderness. He speaks with the affection and solicitude of an old man soon to die, and with a freedom, boldness, and vehemence which none could freedom, boldness, and vehemence which none could have used but one who had done so much for the people whom he addressed, and one who was anxiously desirous for its future welfare. The tone of the law fulls here considerably in the background, and the individuality of the lawgiver and his peculiar relation to the people stand out more prominently. He is taken up with their inward concerns and future fate, laying before them the good effects that will follow the ob servance of the law, and the evil consequences that will infallibly result from its neglect. Most of those to whom it was more immediately addressed had not seen many of the wonders of God, or had been too young to understand them; and hence the sacred historian begins by recapitulating the various mercies which God had bestowed upon them and their forestands from their dear turn out form.

ing promises made to them by God, which he would assuredly perform if they did not frustrate his designs of mercy by their own wilful obstinacy. That no person might thereafter plead ignorance of the divine law, he commanded that it should be read to all the people at the end of every seventh year; and con-cluded his ministerial labours among them by a most beautiful ode, and by giving his benediction to the several tribes. In the last chapter, which is commonly several trioes. In the last enabler, which is commonly ascribed to Joshus, we have an account of the last days of Moses; how, from the top of Mount Nebo, he surveyed the promised land; and then, having died in Mosh, was buried by God himself, so that no one in Mosh, was buried by God himself, so that no one knew his tomb. This book contains only one prophecy relative to the Messish, but a number of very remarkable predictions relative to the future of the Jews.—

Ref. Horne's Introduction to the Holy Scriptures.

DEUTEROPATHIC, du'-te-ro-puth'-ik (Gr. deuteros, second, and pathos, suffering), is applied, in Med to an affection induced in a part through sympathy with the part originally affected; as, where the stomach is disturbed through a wound in the head.

DEUTOSIDE, du'-toks-ide (Gr. deuteros, second, and coxide), in Chem., the oxide of a metal containing a double dose of oxygen. The word binaxide is, however, more generally used. This remark applies to all compounds commencing with the word deuto.

compounds commencing with the word deuto.

DRUTZIA, de-ut'-ze-a, in Bot., a gen. of plants belonging to the nat. ord. Philadelphace. The leaves of some species, especially those of D. scabra, are covered with beautiful scales; hence, from their roughness, they are used in Japan for polishing purposes.

DEVELOPMENT (See PHYSIOLOGY.)

DEVELOPMENT THEORY, de-vel'-op-ment the'-o-re (Er. développer, to develop; théorie, theory), a theory originally propounded by the author of a work entitled "Vestiges of the Natural History of Creation," published in the year 1844. In this work the author first states that animal and vegetable life have progressed gradually on the globe. With regard to animal life, and arguing from fossil remains, he places the order or progression as follows:—First, an era of invertebrate animals; second, a period during which fishes were the only vertebrate form of being; then a period when reptiles were seen in addition, but without birds or mammalis; next a time when the last were added, but without way, and facility the present of the process of t without man; and finally, the present era, in which that master species has existed in supremacy over all. Taking creation, then, as a broad course of progressive organization, the theory of development is thus set forth:—All animal and vegetable organisms commence with a simple cell, of which it is impossible in any case to tell to what form it is destined to advance. A series of changes takes place, by the careful examination of which it is possible to determine to which class the future animal or vegetable will belong. According to the theory as enuncisted by Von Bär, "a heterogeneous, or special structure, arises out of one more homogeneous or general, and this by a gradual change." At the same time it is contended that the embryo of each grade of being passes through the general condi-tions of the embryos of the grades beneath it. In an embryo of the vertebrate sub-kingdom can be traced the change which will determine whether it will belong to the fish, reptile, bird, or mammal class. In an embryo of the mammal class, the characters of the particular order are next determined; and afterwards those of the family, genus, species, sex, and individual in succession. As an illustration,—"There is no essen-tial difference between the vertebral column of the early embryo of man and that of an embryo fish; the evolution of the nervous centres begins, in both, on the same plan; so also does that of the circulating apparatus." Comparing the changes through which the embryo passes, with the history of the general life of the globe, a strong similarity in the plan is to be observed in the individual life of every one of the forms of organized beings which now people it. There has been a succession from invertebrate to vertebrate; from the fish to the reptile, from the reptile to the bird which God had bestowed upon them and their forefathers from their departure out of Egypt,—the victories is
which, by divine assistance, they had obtained over
their enemies,—their rebellion, ingratitude, and chastisements. The moral, ceremonial, and judicial laws
tree repeated, with additions and explanations; and
the people are urged to obedience in the most affect
the people are urged to obedience in the most affect
the people are urged to obedience in the most affect
the people are urged to obedience in the most affect
that a chemico-clotric operation, by which germinat
tionate manner, from the consideration of the endearorganic creation, and that the second was an advance of these through a succession of higher grades, and a variety of modifications, in accordance with laws of the same absolute nature as those by which the Almighty rules the physical department of nature. The theory of development was strongly and ably opposed by Mr. Hugh Miller, Professor Sedgwick, Dr. Hitchcock, and others, who argued that it was immoral and anti-Christian to doubt the generally received theory of creation by law; namely, that every event in nature takes place by fixed and not by progressive law. Notwithstanding the strong opposition the theory has received, it has gained many supporters. Since the organic creation, and that the second was an advance received, it has gained many supporters. Since the year 1859, when Mr. Darwin published his "Origin of Species by Natural Selection," the subject has excited much attention. In this work Mr. Darwin brings forward an hypothesis of the becoming of new species, founded on the modifiability of which animals are seen to be capable under breeding. The principal suggestion in the work is, that in the struggle for existence among the multitudes of animals, any variety which was better adapted for the circumstances than its com-panions, would live and increase while the other-declined. He thus traces all animals back to four or five primitive types, rejecting the theory of develop-ment, and referring all the phenomena to an advance or improvement in progress.—Besides the works referred to, see Explanations, a Sequet to Vestiges, &c.; and Edinburgh Review, April, 1860, art. Darwin on the Origin of Species.

DEVICE, de-vise' (Mediæv. Lat. divisa, a design), the name given to any emblem selected by a person, family, or body of men, to serve as a mark of distinction. The device is often accompanied by a motto, and is similar in purpose to the crest, or any charge in a coat of arms. It differed, however, from the family crest of the hearer, in having some characteristic in allusion to his name, character, or some enterprise in which he was implicated or about to encare. The cruss in a was implicated or about to engage. The cross, in a variety of forms, was the common device of the Crusaders; the sprig of broom (planta genista) was the device of the Plantagenets; the red and white rose, respectively, were the devices of the rival houses of York and Lancaster; while the rose and portcullis, and rose and crown, were the emblems of the house of

Tudor.

DEVIL, dev'-l (Gr. diabolos, false accuser; Heb. Satur, adversary), is the name commonly given in the New Testament to the arch-fiend, who is represented as being in constant opposition to God, and the ruler of a host of evil spirits like himself. Originally created good, he and his followers fell into sin, and so became wicked and malicious. Retaining many of his original qualities, he became a powerful instrument for evil. He was the means of deceiving our first parents, and leading them into sin, and thus brought sin and suffer-ing into this world. There are various other names ing into this world. There are various other names applied to the devil in Scripture. There are some persons in the present day who deny the personality of Satan, and regard him only as an evil principle. Such an opinion can only be held by doing the utmost violence to the language of Scripture. He is everywhere the probability of the proposal evil. where there spoken of as having a real personal existence, as being in a state of constant activity, possessed of power and dominion, and as having measengers and followers. He is held accountable, is charged with guilt, and is to be judged and receive final punishment. How, on any such idea, Christ's temptation in the wilderness can be accounted for, we cannot see. If we believe in the existence of good spirits (and there is certainly no reason to think that man is the highest creature in the scale of being, there is no reason to doubt the existence of evil spirits. Scripture speaks as plainly and decidedly regarding the existence of the one as of the other.

DEFINE, de-vise (Fr. deviser, to imagine or invent), in Law, is the act whereby a testator conveys his lands by will, the conveyance of personal property being commonly termed a bequest. (See WILL.)

DEVORIAN SYSTEM. (See OLD RED SANDSTONE.)

DEW, dew (Sax. deaw), the moisture or aqueous vapour which is deposited from the air on those bodies which are exposed to it. It is generally observed in the form of minute globules on the surfaces of leaves. When the cold is extreme, it takes a solid form, and

appears as hoar-frost. When the atmosphere is at any given temperature and pressure, it holds a proportionate quantity of aqueous vapour in suspension. temperature is lowered to a certain point, called the temperature is lowered to a certain point, called the dew-point, a quantity of aqueous vapour is set free in the form of water or dew, which can sometimes be seen falling as a fine rain or mist. Those substances which radiate heat rapidly are cooled soonest; and therefore the dew is deposited upon them first. All vegetable fibres are ready radiators of heat; consequently, the smooth leaves of trees, shrubs, and grasses cause the smooth leaves of trees, shrubs, and grasses cause the dew to be deposited upon them even upon moderately warm evenings. Radiation takes place most rapidly when there is a clear sky: when there are many clouds in the air, heat is radiated back by them to the earth, which nearly supplies the amount of heat lost. Thus dew is more readily deposited upon clear fine nights than when the sky is overcast. The history of the knowledge of dew is interesting. Aristotle supposed that there was a rain formed by the condensation of the water which had been evaporated during the day, by the cold of night. (Meteor. i. 10.) In 1784, however, the recognized opinion was, that the cold was caused by the dew. It was not until the discoveries of Leslie concerning radiant heat, in 1794-5, that the

of Leslie concerning radiant heat, in 1794-5, that the true theory of dew was established
DEW-POINT. (See DEW.)
DEXTRIN, deks'-trin, in Chem., a transparent brittle solid, with a vireous fracture, formed by submitting starch to a heat of 400° Fah. Dextrin is a modification of starch, possessing the same composition, but dif-ferent properties. It is, for instance, soluble in cold water, a property which renders it particularly valuable for manufacturing purposes, under the name of British gum (which see). It has received the name of British gum (which see). It has received the name of British gum (which see). It has received the name of British gum (which see). It has received the name of British from causing the rotation of a polarized ray from left to right. It may be always distinguished from starch by not giving a blue colour with iodine; and from gum, by giving a blue solution with potash and sulphate of

DEX, dai, is a Turkish title of dignity, now applied only to the ruler of Tripoli, but formerly borne also by only to the ruler of Tripoli, but formerly borne also by the ruler of Tunis, and, prior to its conquest by the French, by that of Algiers. The word is of doubtful origin; but, according to some, it is from the Turkish dai, a maternal uncle, to denote the high esteem in which the rulers of these countries were held by the

Porte.

DIABETES, di-ŭ-be'-tees (Gr. dia, through, and bainomai, I pass), in Med., is a disease characterized by an inordinate flow of trine. Medical men recognize two distinct kinds of diabetes, - the diabetes insipidus, in which there is merely a greatly-increased flow of urine; and diabetes mellitus, in which the urine is found to contain a large quantity of saccharine matter. Persons of a debilitated constitution, and in the decline of life, are most subject to this disease. It commonly comes on slowly and imperceptibly, without any apparent disorder of the system, and may exist for a considerable time before it attracts any notice. One of the most constant symptoms of this disease is an inordinate degree of thirst; and yet the quantity of urine passed daily is usually much greater than that of the plassed daily is usually much greater state state of the liquids drunk. A vorscious appetite is also a usual characteristic of this disease. At length the constitution manifestly suffers, the body becomes emaciated, the strength and vigour fail, the pulse is frequent and small, a slight degree of fever prevails, and the skin is dry and rough. There are also usually sching pains in the back and loins, and uneasy sensations along the urinary passages. The symptoms gradually become urinary passages. The symptoms gradually become more and more intense, until at length the patient sinks from exhaustion, or is cut off by dropsy, consumption, or some other incurable disease. Of the causes or treatment of this disease, unfortunately, little is known. It may be produced by intemperate habits, or whatever tends to impair the system and produce debility. In general, the kidneys are found in a diseased state after death, though in some cases no traces of disease could be found in these or any of the other uninary organs. In fact, as yet little is known the other urinary organs. In fact, as yet little is known of the true character of this disease. The measures resorted to in its treatment are rather of a polliative than a remedial nature; for the general opinion among physicians is, that it is incurable. It is possible, how-

#### Diadem

ever, by judicious treatment, to greatly mitigate the symptoms, and to ward off the issue for a number of years. The treatment should be principally directed to restoring and strengthening the tone of the system, to restoring and strengthening the bone of the system, by abundant exercise in the open air, and the use of tonics and such medicines as tend to scothe the nervous system. The state of the skin is particularly to be attended to; and daily ablution of the whole body in warm or cold water is recommended. The Turkish bath, it is believed, might possibly prove useful in this disorder. Flannel should also be worm next the skin. Those kinds of food that contain sugar, or matter easily convertible into sugar, are to be as much matter easily convertible into sugar, are to be as much

matter easily convertible into sugar, are to be as much as possible avoided.

Diadem, di'-ā-dem (Gr. diadema, a fillet), originally a band of silk or woollen, according to some authorities invented by Bacchus, to relieve the headache produced by intoxication. It was probably imported into Greek costume from the East, and afterwards became the distinguishing ornament of royalty. The diadem of the Egyptian deities and kings bore the symbol of the sacred serpent. Among the Persians it was twined about the tiaras of the kings, and was purple and white. In the earliest times the diadem was very approve but, broad diadems were introduced by the marrow; but broad diadems were introduced by the Persians, and adopted by Alexander the Great. The early Roman emperors abstained from the use of this ornament, to avoid giving offence to the people by calling up the remembrance of the kings. Constantine the Great was the first who used it; and after his time it was ornamented with a single or double row of

DIERRESIS, di-er'-c-sis (Gr. diaireo, I divide), in Gram., is the dividing of a diphthong or of a contracted syllable into two syllables, and is usually denoted by two dots, thus (\*\*), over the last vowel; as avenged, beloved. Sometimes the mark of discress is used to show that two vowels coming together do not form a

diphthoug; as reiterated.

Diagnosts, di-ag-no'-sis (Gr. diagignosko, I discern or distinguish), is the art of discovering the nature of a disease, and of distinguishing it from other diseases of a similar nature. Much depends upon a correct diagnosis of disease; and the minute characteristics that frequently distinguish one disease from another render it often a matter of great skill and delicacy. If the true nature of a disease be not ascertained, a course of treatment may be pursued that may be followed by very serious results.

DIAGONAL, di-hy'-o-nal (Gr. dia, through; gonia, an angle), a straight line drawn from any angle to an opposite one in a rectilineal figure. A straight line iwn between two adjacent angles would obviously coincide with the boundary-line; consequently no triangle can have a diagonal. A quadrilateral figure has two diagonals, a pentagon five, a hexagon nine, &c. In order to calculate the number of possible diagonals in a given figure, the plan is, to take three from the number of sides, multiply the remainder by the number of sides, and take half the product. Thus,-

In the case of a pentagon, 
$$\frac{2\times5}{3}=5$$
, and

In the case of a horagon,  $\frac{3\times6}{2}=9$ .

DIAGRAM, di'-ageram (Gr. diagramma), a drawing delineated for the purpose of demonstrating the properties of any geometrical figure; such as a triangle, a circle, a square, &c.

DIAL. (See SUNDIAL and HOBOLOGY.)

DIALECT, di'-d-lekt (Gr. dialegesthai, to converse), a term applied to a language which resembles another in its general features, but differs from it in details. The two most widely-spread families of languages in the world are the Indian-Gothic and the Semitic. In the former are included the Sauscrit, Zend, Armenian, Greek, Latin, Lithuanian, Sclavonian, Teutonic, and

# Dialogue

peculiarity is called patois, and in England provincialism

DIALECTION, di-M-lek'-tike (Gr. dialektikos, from dialegomai, I discourse), is the old name for logic, or the art of reasoning and disputing justly. According to Socrates, dialectics were so called from being an inquiry pursued by persons who take counsel together, separating the subjects considered according to their kinds. There were several systems of dialectics among the ancients. The dislectics of Plato are a kind of analysis to direct the human mind by dividing, defining, and bringing things to the first truth; which having reached, it applies itself to explain sensible things, but can rest. The dialectics of Aristotle comprise the doctrine of simple words, delivered in his book of Predicaments; the doctrine of propositions, contained in his book "De Interpretatione;" and that of the several kinds of sulprises may be hooked of Arabytics several kinds of syllogism, in his books of Analytics, Topics, and Elenchuses. The dialectics of the Stoics Topics, and Elenchuses. The dialectics of the Stoics appear to have been little more than a system of

grammatical rules. (See Logic.)

Dialityst, di-ai'-le-um, in Bot., a gen. of leguminous plants. The only remarkable species is D. indicum, which yields a fruit called the tamarind plum, the pulp

of which has an agreeable slightly acidulous tasts, somewhat resembling that of the common tamarind. DIALLAGE, di-al-lij (Gr. diallege, difference), in Min., a foliated silicio-magnesian mineral, so called from its changeable colour.

DIALLOGITE, di-nil'-lo-jite, in Min., a carbonate of

DIALLOGITE, di-ill-lo-jite, in Min., a carbonate of manganese, occurring in crystalline masses of a rose-red colour. It is found chiefly in gueiss and porphyry veins, with silver, lead, zinc, and other ores. It is found in Saxony and Transylvania.

DIALOGUE, di'-āl-og (Gr.), is a conversation between two or more persons, usually upon a particular subject, and conducted with more formality than an ordinary conversation. The ancient philosophers were fond of conveying their instructions in this form, and some of their principal works that have come down to some of their principal works that have come down to us are in dialogues. Plato is particularly distinguished for the heauty of his dialogues, which, for richness and for the beauty of his dialogues, which, for richness and power of imagination, are unrivalled, and have often been compared to the conversations of the gods. The dialogues of Cicero, as "De Oratore," are agreeable and well supported; but the style is sometimes profix and heavy, and the orator too often peeps out in them. Lucian is also distinguished as a writer of dialogues full of pleasantry and satire. In modern times we have the learned and cluborate dialogues of Erasmus, in Latin, besides whom there are among the Gare. have the learned and claborate dialogues of Leasmus, in Latin; besides whom, there are, among the Germans, Lessing, Mendelssohn, Herder, Jacobi, Schelling, &c.; Petrarch and Machiavelli, among the Italians; and Fánelen, Fontenelle, Malebranche, and Sarrassin, among the French. In England we have the "Divince Dialogues" of Henry More; the "Visions of Heaven and Hell," said to be Bunyan's; the "Philosophics! Dialogues." of Barkeley, the dialogues of martral religions. and Hell," said to be Bunyan's; the "Philosophical Dialognes" of Berkeley; the dialognes on natural religion of Hume; the moral and politionl dialognes of Bishop Hurd; Lyttleton's "Dialognes of the Dead;" and many others. Still more recently have appeared Southey's "Colloquies on Society;" Walter Savage Landor's "Imaginary Conversations;" Help's "Friends in Council;" and Professor Wilson's "Noctes Ambrosiane." To write in dialogue is by no means so casy a task as is commonly imagined. It requires more than merely the introduction of different persons speaking in succession. It ought to be a natural and speaking in succession. It ought to be a natural and spirited representation of real conversation, exhibiting the character and manners of the several speakers, and suiting to the character of each that peculiarity of thought and expression that distinguishes him from others. From a dialogue thus conducted, the reader receives a fair and full view of both sides of the argument, and is at the same time entertained with polite conversation, and with a display of consistent and well-supported characters. Such a production stands high among the works of taste. The so-called Socratio Greek, Latin, Lithnanian, Sciavonian, Teutonic, and Ingh among the works of taste. The so-caused coerasic Celtic dialects. In all these, the resemblance, although dialogue is a conversation in the form of question and often far distant, is able to be traced. The Semition answer, in which the questions are so contrived, that embraces the Hebrew, Syriac, Arabic, and other dialects not a well known. The differences of speaking the person questioned is led to come to the very conclusion that the questioner wishes to bring him. "There the same language in the same country do not properly are some questione," says Hame, "to which dialogue come under the head of dialects. In France any such writing is peculiarly adapted, and where it is preferable

to the direct and simple method of composition. . . Any question of philosophy which is so obscure and uncertain that human reason can reach no fixed determination with regard to it, if it should be treated at all, seems to lead us unturally into the style of dialogue and conversation. Reasonable men may be allowed to differ where no one can reasonably be positive; oppo-site sentiments, even without any decision, afford an agreeable amusement; and if the subject be curious and interesting, the book carries us in a manner into company, and unites the two greatest and purest pleasures of human life,—study and society." He also considers it useful in handling points that are so obtained to the company and the second considers of the second considers and we are important to the second considers. ous as not to admit of dispute, and yet so important that they cannot be too often inculcated; the vivacity

that they cannot be too often inculcated; the vivacity of conversation serving to enforce the precept, and give it novekly and beauty, from the various lights in which it is presented by the different personages.

DIALYSIS, di-dil-e-sis (dia, through, and luo, I set free), in Chem., a method invented by Mr. T. Graham of separating the crystalloid and colloid constituents of solutions, by taking advantage of the property possessed by the former of passing through a septum of colloid matter. (See DIFFUSION or LIQUIDS.) It is generally effected by means of an instrument calle' a dialyser, which consists of a hoop of gutta-percha covered with a sheet of parchmentized paper strained tightly, and kept in its place by an india-rubber band. The solution to be dialyzed is poured into the dialyser to the depth of half an inch, and the whole is floated in a basin of pure water. The crystalloids floated in a basin of pure water. The crystalloids contained in the liquid diffuse themselves through the parchment-paper into the water below, but the colloids are retained behind the colloidal parchment-paper, being impervious to them. A mixture of common salt being impervious to them. A mixture of common sair and gum placed in the dialyser for thirty or forty hours parts with the whole of its sait, the gum being left behind in pure condition. Other substances besides parchment-paper may be used; such as a layer of albumen brushed on writing-paper and coagulated by beat, or a film of animal mucus laid between two pieces of linen. Dialysis promises to be of the greatest use in separating crystalline principles, such as the alkaloids, from vegetable infusious. It may also the airsholds, from vegetable infusions. It may also be applied to the detection of crystalline poisons, such as arsenic or strychnine, in animal mixtures, no matter how heterogeneous the compound may be. It also throws great light on many obscure points in animal physiology. The ready absorption of crystalline matters by the stomach, which is a membrane covered with colloid mucus, and the reparation thus effected of the crystalloid and colloid portions of the food, are instances of dialysis going on in the human frame. Another example is the tongue, the mucous membrane of which readily transmits crystalloid salt and sugar to the nerves of taste; while gum, starch, and other col-loids, are either rejected altogether or only feebly ab-sorbed. For a full account of Mr. Graham's experisortical. For a time account of mr. Gramam s experiments on dialysis the student is referred to a paper on the subject, in the "Philosophical Transactions" for 1862, part I., which is one of the most masterly scientable memoirs ever written.

thic memoirs ever written.

DIAMAGNETISM. (See MAGNETISM.)

DIAMETER, disan'e-ter (Gr. dia, through; metron, a measure), a term generally applied to the line drawn through the centre of a circle, and bounded at either end by the circumference. Whenever any point is

end by the circumference. Whenever any goint is called a centre, any straight line drawn through that point is generally called the diameter.

DIAMIDE, di'-u-mide, in Chem.—A diamide is a substitution compound of ammonia, in which two equivalents of bydrogen in a double equivalent of ammonia are replaced by one eqvivalent of an element or radials. diela.

DIAMINE, di'-a-mine, in Chem., a diamide with basic

properties capable of forming salts with acids.

Diamond, di'-ā-mond, in Min.—The word diamond is derived from the Greek adamas, unconquered, in allusion to its extreme hardness. Chemically speaking, diamond is pure crystallized carbon. As found in nature, diamonds occur crystallized in forms belonging to the regular system. The crystals are mostly derived from the octahedron; but the faces are frequently convex, and the edges rounded. In their rough state they present the appearance of sensi-transparent rounded RL

pebbles, covered with a thin brownish opaque crust. Rreed from this coating, they are generally coleuriess; but they are also found tinged with red, orange, yellow, brown, and black. The pure white transparent variety are most highly prized, and are called diamonds of the first water. The finest diamonds occur in quartzose alluvial deposits at Golconda and Bundelound, in India, where the finest specimens have been found; also in Borneo, in several districts in Brazil, in the Ural mountains, in Russia, and in one or two other unimnortant Borneo, in several districts in Brazil, in the Ural mountains, in Russis, and in one or two other unimportant localities. The origin of the diamond in nature is at present unknown. It is, however, evidently of vegetable origin. Diamond is the hardest body known, and can only be cut or polished by means of its own powder. The powder is mixed with oil, and spread on a revolving steel disk, and the diamond, which is attached with solder to a suitable support, is held against it until a facet is formed. It is then unsoldered, fixed in a different position, and a second facet ground. The most remarkable diamonds with which we are acquainted, are the diamond mentioned by Tavernier, as belonging to the Great Mogul, which is said to have weighed 900 carates in the rough state; the diamond amongst the Russian in the rough state; the diamond amongst the Russian crown jowels, weighing 195 carats; the famous Pitt diamond, which weighs 196 carats. This diamond is, from its lustre and colour, considered the finest known. The Kohinoor belonging to the queen, weighed 213 carats, but was badly cut. It was re-cut in 1852 by Messrs. Gunard, and now weighs 147 carats; but is greatly improved in brilliancy, although lessened in size. Diamonds are valued at so much per carat of four grains, and increase in price in a given proportion. The general rule for finding the value of cut diamonds, is to double the weight in carats, and multiply its square by £2. This rule does not apply to diamonds weighing out by cleavage through the natural planes of the crystal. A distinguished English philosopher made a crystal. A distinguished English philosopher made a large sum of money by buying flawed diamonds at a low price, and cleaving them into smaller gems. The principal use to which diamonds are applied, besides as articles of ornament, is for cutting glass. For this purpose, the natural curved edge is used. Writing diamonds are either sparks with natural or accidental points, or diamonds ground to a conical point. Diamond-dust is employed for grinding the faces of other gems. Diamonds are inflammable when heated reduct and shunged into an expendence of Gyrgen burns. hot, and plunged into an atmosphere of oxygen, burning with a steady light, and giving rise to pure carbonic acid. They are not, however, perfectly pure, a small residue being left behind, containing silica and iron.

The specific gravity of diamond is about 3.34.

DIAMOND REELES, a name usually given to Entimus imperialis, a species of the tribe Curculionida (weevils), and order Coleoptera, found abundantly in Brazil. It is polished black in colour, the head, thorax, and limbs being slightly granulated and covered with metallio

DIAMOND BEETLE.

green scales, and the wing-cases (elytra) studded with regular lines of concavities, each depression thickly lined with bright green scales, so that the rays of light are reflected and heightened by the contrast of the shining black interstices. The genus Entisus is entirely exotic; but there are small species of the genera Polydrosus and Phyllobius common in England, orns-

#### Dismond Necklace

mented with similar scales, but not presenting the gem-like spots. The elytra of the diamond-beetle are sometimes made into head-dresses, &c., for ladies; but the most general use of the insect is as an object for

the microscope.

DIAMOND NECKLACS, THE, a famous piece of jewellery, made by a man named Boehmer, in Paris, about the years 1744-45. According to Madame Campan, it was originally intended for Madame Du Barry, the favourite of Louis XV. On the death of the king, in 1744, Du Barry was compelled to leave the court, and Boehmer was left with the necklace on his hands. It was a wonderful and costly piece of work, consisting of 500 diamonds. Its value was said to be 1,800,000 for any one to buy it. A woman named De Lamotte, who waited about the court, having heard of these circumstances, contrived to persuade the Cardinal Prince Louis de Rohan, a vain profligate man of great wealth, that Queen Marie Antoinette did not look upon him with disfavour. The vain cardinal, readily believing this, was ready to do anything to retain the regard of the queen. He was persuaded by Do Lamotte that Marie Antoinette was extremely anxious to possess the diamond necklace; but not having enough money then, she was willing to sign an agreement to purchase it, if the cardinal would become security. Rohan did consent, and signed the agreement, security. Rohandid consent, and signed by the queen. On the 1st of February, 1786, the necklace was handed over to him, and he took it to Versailles, the place where the queen had undertaken to send for it. All this time the cardinal had never seen the queen, although, by a stratagem of De Lamotte's, he imagined that he had met her for a few moments at midnight in the park of Versailles, and all the messages, written and verbal, had come through the woman De Lamotte. On the day after he arrived at Versailles, a man dressed in the uniform of the court valets came to his apart-ments, and took away the necklace, saying, as he did so, that it was " in the name of the queen.' Almost imthat it was "in the name of the queen." Almost immediately afterwards, De Lamotte, her husband, and the sham valet, left Paris. The whole transaction had been a deception and a swindle. The verbal messages from the queen were all false, and the written one forgeries by the sham talet, who was an adept at imitating handwriting; and the woman whom the cardinal had met in the park of Versailles was not the queen, but an unfortunate of Paris, named Gay d'Oliva, who but an unfortunate of raris, named day d'ava, mo had been hired by De Lamotte for the purpose. The plot was discovered by Boehmer, who, when he found that he was not paid when the period for the first instalment arrived, inquired at the court if the queen had received the necklace. This arcused suspicion, and inquiries being instituted, the cardinal and the persons associated in the plot were arrested and sent to the Bastille. The trial lasted nine months, and sentence was given on the 31st of May, 1786, when all were acquitted except Lamotte, who was branded on the shoulder with the letter V, for volcuse, thief. When the cardinal got out of the Bastille, at ten o'clock at night, large mobs hurrahed round him, out of spite to the court. It was the beginning of the Revolution. Seven years afterwards Marie Antoinette was led to execution, and the yelling and cursing mob taunted her with the scandal of the diamond necklace a few moments before she died.

DIANTHUS, die d'itales (Gr. anthos, flower; dios, of Jupiter,—the divine flower), in Bot., a gen. of plants belonging to the nat. ord. Caryophyllaces. Many of the species are highly valued for the beauty and the fragrance of their flowers. D. barbatus, the sweet-william, is an old inhabitant of the flower-garden, and was much esteemed in Gerarde's time "for its beauty was much esteemed in Gerarde's time "for its beauty to deck up the bosoms of the beautiful, and garlands and crowns of pleasure." The flowers grow in fascicles, and are usually of a fine orimson colour. There are numerous varieties in cultivation. The species D. curyophyllus, which grows wild on old walls in the south of England, is supposed to be the source of the garden carnations, and, by some botanists, of the Thike also. The carnation has been cultivated from this immerancial in Europe, and its heavy and rich time immemorial in Europe, and its beauty and rich spicy odour make it a general favourite. It is the principal florist's flower of Germany and Italy, from

## Diaper-work

which countries we derive the choicest varieties. varieties of the carnation are arranged in three classes, -flakes, bizarres, and picotess. Flakes have two colours only, the stripes being large; bizarres (Fr., odd or irregular) are variegated in irregular spots and or irregular) are variegated in irregular spots that stripes, with no less than three colours; picotees (Fr. piquettie, pricked or spotted) have a white ground spotted or pounced with red, purple, or other colours. The garden cloves have petals of a deep scarlet colour, and are derived, like the varieties of the carnation. from D. caryophyllus. The pink, as a florist's flower, received but little attention until the close of the last century, but many fine varieties have been developed since then. Being one of the hardiest and least expensive of fine flowers, it is much cultivated by opera-tive mechanics and manufacturers round large towns. The varieties most esteemed are those called pheasant's eyes, which seem to have sprung from D. plumarius. New varieties of the carnation and pink are procured from seeds, and thousands of seedlings are annually blown by florists and amateurs, though it frequently happens that there are not more than two or three worth keeping. Established or approved varieties are continued by layering and by cuttings, or, as they are commonly called, pipings. The soil in which they commonly called, pipings. The soil in which they thrive best is a rich loam, rather sandy than otherwise.

DIAFASON, di-a-pai-zon (Gr. dia, through; pas, all), in Mus., an ancient Greek term for the interval of the octave. It is also the name of a kind of rule by which certain instrument-makers determine the measures of the various parts of their instruments. Some of the stops in the organ are called by this appellation, be-cause they extend through the entire instrument. Dryden makes use of the term in one of his finest metaphors,-

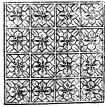

"From harmony, from beavenly harmony, This universal frame began; From harmony to harmony Through all the compass of the notes it ran, The diapason closing full in man.

DIAPENSIACE E, di-ap-en-se-ai'-se-e (Gr. dia, through; pente, five ; in allusion to their being five-cleft), in Bot., a small nat. ord. of dicotyledonous shrubby plants in the sub-class Corolliflora. There are but two genera and two species, the properties and uses of which are unknown. They are natives of North America and unknown. They northern Europe.

DIAPER, di'-ap-er (Fr.), a kind of textile fabric, either of linen or cotton, or a mixture of the two, with a figured pattern on the exterior surface, produced by a peculiar method of twilling. Diapers are much used for table-linen and fine towels. With the exception of damask, diapers are the most ornamental kind of twilled cloths. There is some controvers as to the origin of the term diaper. According to Mr. Planché, it is derived from d'Ipres, that is, "of Ypres," a town is Flanders famous for its manufacture of rich stuffs and fine linen before the year 1200. Ducange derives the of its shifting lights; but the former is the most probable derivation.

DIAPER-WORK, or DIAPERING, in Arch., is a mode of decorating a surface by covering it with the constant

repetition of a small flower, leaf, or other or-nament, either carved or painted. If carved, the flowers are entirely sunk into the work below the general surface. are generally square, and placed close to one another; but in some cases other arrangements are used, as in Canterbury cathedral. Disper deco-ration was first intro-duced in the Early Eng-

duced in the Early Eng.

lish style, in which it was tometimes employed to cover large spaces, as in Westminster Abbey and Chichester cathedral. It was also extensively used in the Decorated style. Diaper-work was only used as a painted ornament in the Perpendicular style, and very few specimens of it remain. Some portions of a pattern of

# Disphanous Bodies

beautiful flowing foliage are to he seem in the Lady chapel in Gloucester cathedral.—Ref. Parker's Glossary of Architecture.

DIAPHANOUS BODIES. (See LIGHT.)

DIAPHORETICS, di-d-fo-red-its (Gr. diaphoreo, I carry through), a name given to medicines that increase the natural exhalation of the skim. When they are so powerful as to produce actual perspiration, they are called audorifics, the difference between the two classes being only one of degree, not of kind. They are classes being only one of degree, not of Killd. They are in general used to restore the cutaneous discharge when it has been suppressed through cold, and are hence useful in catarrh, rheumatism, or diarrhon proceeding from cold. Among the more common diaphoretics are antimony, ipecacuanha, ammonia, opium, guiacum, camphor, and contrayerva. A dose of Dover's powder, with warm drinks and plenty of blankets in bed, usually predices acousing paragraphic and is yety beneficial. produces copious perspiration, and is very beneficial in colds.

DIAPHEAGM, di-a-fram (Gr. diaphragma, 8 parti-tion), in Anat., is the name given to that transverse muscle which separates the thorax or chest from the abdomen or belly. It is usually described as consisting of two muscles. The superior and larger of these arises from the ensiform cartilage of the sternum, and the ends of the lower ribs on each side; from which points the fibres converge, and terminate in a tendon. or aponeurosis, termed the centrum tendinosum, or central tendon. The second and inferior muscle springs from the vertebræ of the loins by two productions, or crura; that on the right side from the four upper lumbar vertebræ, that on the left from the three upper ones. From these points the fibres ascend, some of them crossing over and decussating to surround the esophageal opening; but all of them ultimately uniting with the central tendon, and thus making but one muscular partition. The diaphragm is convex superiorly and concave inferiorly, and is covered on it apper side by the pleura, and on the lower by the peritongum. In form it is nearly circular, and is fleshy at the edges, but becomes tendinous towards the centre.

It presents three large openings and several smaller ones. The opening of the vens cava is quadrangular ones. The opening of the vens cars is quadrangular in form, and is situated in the tendinous centre. The cesophagesl opening is posterior to that of the vens cava, and is of an elliptic form. The sortic opening is the most posterior, triangular, and between the crura. This muscle is the principal agent in respiration; for by contracting it enlarges the cavity of the chest, and allows the lungs to receive the air in inspiration, while by being relaxed, the cavity of the chest is again diminished, and the air suddenly expelled. The contracting and relaxing of this muscle must likewise, it is evident, have a similar effect in increasing and diminishevident, have a similar effect in increasing and diministing the size of the abdominal eavity; and hence, by its action upon the stomach and intestines, it sids in the expulsion of the fæces and urine. The diaphragm is largely engaged in laughing, seczing, sighing, schling, and other affections of the respiratory organs. Whatever occasions stoppage of the action of this muscle speedily proves fatal. It is subject to influmnation, called diaphragmativis; but as this is rarely confined to the organ itself, but communicated either to the pleurs or peritoneum, its symptoms and mode of treatment correspond with inflammation of these parts. (See PLEURITIS and PERITONITIS.)

DIABERGA, di-ar-re'-a (Gr. dia, and rheo, I flow), is a disease characterized by an increased discharge from the bowels, usually in a very liquid state, and sometimes containing a large quantity of bile. This disease may be occasioned by anything that stimulates or irritates the mucous surface of any portion of the alimentary canal. Besides the various purgative medicines, undressed or indigestible foods or vegetables, acid fruits oily or putric substances, frequently cause diarrhos. Suppressed perspiration, occasioned by a sudden chill or cold applied to the body, or a draught of any cold liquid when overheated, may produce it. It is more apt to occur during the summer and autumn months than at any other period of the year. The effluvia arising from the decomposition of organic substances is a frequent cause of it. It sometimes results from the irritation caused by worms, or by some organic disease, and is a common symptom of the advanced state of consumption. Besides looseness of the bewels, this disease is

#### Diatomaces

usually accompanied with griping and flatulency, together with an uneasy sensation in the lower part of the abdomen. There are frequently, also, nauses and vomiting, a bitter taste in the mouth, a furred and yellow tongue, dry and harsh skin, a pale or sallow countenance, and, if not speedily checked, great emaciation. Physicians distinguish various kinds of dischlored and the statement of the diarrhoa; as crapulosa, when the faces pass of ordinary quality, but immoderately loose and copious; biliosa, when the bile is more abundant than natural; mucosa, when the excrements contain a quantity of mucus; serosa, in which they are almost entirely iquid and watery; and lienteria, when the food passes through the body in an almost unaltered state. This is one of those diseases by means of which nature strives to get rid of impurities, and restore the system to its normal condition. Hence, when it is not very violent, and when the patient is strong, it is best to allow it to run its course, at all events for a time, and even to sid it by small doses of laxatives. In any case, great care is to be taken not to stop it too suddenly. Sometimes an emetic is of great benefit in removing the cause of irritation. When it arises from obstructed perspiration, a warm bath, or a dose of Dover's powder, and warm clothing in bed, will usually effect a cure. When it is occasioned by a too acid state of the secretions, the great remedy is chalk mixture. Opium is also frequently employed; but it should not be taken in large quantities without medical advice. The treatment thus in all cases depends upon the cause from which it springs.

DIARY, di'a-re (Lat. diarium, from dies, a day), is strictly a daily register or record of occurrences in which the writer has had a personal share, or which have at least in some way come under his own observation. The use of diaries has now become so common in this country that the manufacture of them forms an important branch of trade. They are usually prepared with a blank space for every day of the year, and vary in form and size according to the object they are more particularly intended to serve. Usually one book is in-tended to contain the events of a year. The use of diaries cannot be too strongly recommended. chant and man of business they form a register of transactions and engagements; to the student and man of letters a record of daily readings, thought, and observation. The publication of such diaries as those of Pepys and Evelyn has thrown much light upon the state of society at the time when the writers lived.

Diastase, di-as-tare (Gr. diastass, a separating of parts), in Chem., a peculiar ferment found in all germinating seeds. It is this principle which causes the starch in malt to be converted first into dextrin and then into sugar. When barley is malted, diastance in the starch in the starch in the starch in the second of the starch in the starch in the starch in the second of th and then into sugar. When barley is malted, dis-stase is developed in the grain, which converts the starch into sugar, on the application of heat and water

in the operation of mashing.

Diastole, di'-as-tole (Gr. dia, and stello, I stretch), in Phys., is applied to the dilatation of the heart and arteries, and is opposed to systole, which denotes the

contraction of these parts.
DIATHESIS, di-ath'-e-sis (Gr. diatithemi, I dispose). in Med., is applied to a certain state of body predis-posing it to certain diseases. Thus the scrothless, gouty, cancerous diathesis, denotes a certain constitugonty, canderous distributions, denote a certain favourable conditions or exciting causes, to these diseases.

Diatomack, di-di-on-oi-see (Gr. dia, across; tome, cut), in Bot., the Brittleworts, a fam. of con-

fervoid algae, of very peculiar character, consisting of microscopic brittle organisms, found in almost all fresh, brackish, or salt water, sometimes forming a uniform yellowish-brown layer at the bottom the water, at others adhering to various waterplants, decaying stems, and stones, or scattered be-tween the filaments of Conferve. They also occur smong mosses and Oscillatories, and on damp ground. The individual cells of the Diatomacee are called frus-The individual cells of the Diatomaces are called frustules or testules, and are furnished with an external cost of silica. This fiinty cost, of two usually symmetrical portions or valves, is comparable with those of a bivalve shell, but is in contact, at its margins, with an intermediate piece called the hoop, which varies in breadth according to age. The separate valves are of various forms; as circular, oblong, ellip-

#### Distonic

tical, linear, saddle-shaped, boat-shaped, and undulate; and their broad surfaces exhibit various more or less delieste sculpturings and markings, in the form of bands, lines, either parallel, radiate, or corossing each other, and dots, or a cellular appearance. The Desmidiacea are regarded by Professor Bentley, whose classification we have adopted in this work, as a section of the sub-order Diatomacea; but those writers who have devoted special attention to microscopic plauts make each group a distinct family. The Desmidiacea are found only in fresh water, are generally of a green colour, and are not silicious externally.—in place of colour, and are not silicious externally,—in place of the flinty sheath of the distom, there is a very transparent coat of cellulose. The study of the humble forms of vegetable life included in these two interestforms of vegetable life included in these two interesting families is pursued with great zeal by our leading
microscopists, and new facts are continually being
ascertained respecting their reproduction and movements.—Ref. Micographic Dictionary, by Griffith and
Hentrey; Pritchard's Infusoria (new edit.); Carpenter's Revelations of the Microscope.
Diatonic (Gr. dia, through, and tonos, a sound).—
Of the three scales employed by the ancient Greeks,
that which consisted like the modern system of inter-

that which consisted, like the modern system, of intervals, of major tones and semitones. The diatonic has long been considered the most natural of these three scales. According to Aristoxenus, it was the first; and the other two, viz., the chromatic and enharmonic, were formed from the division of its intervals.

DIATONIC SCALE .- The natural scale, consisting of eight sounds and seven intervals; five of these intervals are called tones, and the remaining two semitones, which occur between the third and fourth and seventh and eighth. The distonic scale is a gradual succession of sounds by tones and semitones, which may proceed either from acute to grave or vice versa, five whole tones and two semitones making a complete natural octave.

DIATRIBE, di'-a-tribe (Gr., a disputation), is generally a continued discourse or disputation, more particularly a bitter and violent attack, either written or spoken, on any subject.

DIBBLE, dib'-bl (Ang.-Sax.), a well-known gardening implement, made of wood, usually about an inch and a half in dismeter, used for making holes for planting seed, &c. It is pointed, and provided with a handle, by means of which it can be more easily pressed into the ground. In some parts of England wheat is planted with the dibble; several dibbles are joined together, and the handle is made of such a length as to enable the man, as he walks backwards, to make the holes: children follow him, and drop two or three grains into every hole. A considerable saving of seed is effected by sowing with the dibble. Dibbles can only be used in light soils; stiff and clayey soils cannot be treated in this way; the soil grows hard round the hole, hindering the shoots from the seed; at the same time it holds water, which is also detrimental.

Dicast, di-kast (Gr. dikastes), a functionary amongst the ancient Greeks, who, with his colleagues, was empowered constitutionally to try and pass judgment upon all causes and questions that the laws and customs of his country pronounced capable of judicial investigation. The dicasts of the Attic democratic period, when they were selected from the people, and when they took an oath that they would well and truly discharge their duties, closely resembled the English discharge their duties, closely resembled the English jury. The conditions of the eligibility of a dieast at Athens were, that he should be a free citizen, in the enjoyment of his full franchise, and over thirty years of age. Six thousand persons were elected for the service every year. The mode of election is not very clearly stated; but it is evident that they were chosen by lot. Before proceeding to his duties, the dicast was obliged to swear the official oath. After the oath was taken, the courts were assigned to the several sections of dicasts. As soon as the allotment took place, each dieast received a staff, on which was painted the letter Every dieast received a fee for his attendance.

They are

Every dieast received a tee for his attendance.

DIGE, disc (Fr. de), the plural of die. They are
small cubes of ivory or bone, marked with black dots
on their sides, marked from one to six upwards. Dice
are placed in a small tubular box, shaken with the
band, and then thrown out. When the dice are per-

# Dictator

fect in their form as cubes, there is no possibility of knowing what number may be thrown; but amongst swindling gamblers loaded dice are often used, which are so constructed as to turn up a certain number when required. The principal game played with dice is hazard. They are also employed in other games of chance; two dice are used in the game of backgammon. chance; two dice are used in the game of backgammon. Lotteries, raffles, and disputes, are also often settled by throwing a pair of dice. By the act 9 Geo. IV. c. 18, a duty of twenty shillings was imposed upon every pair of properly-made dice. This act was passed for the purpose of suppressing gambling, and since that time all dice have been stamped; and any person issuing dice without the government stamp is liable to a remarke

penalty.

DICHORD, di'-chord (Gr. dis, double, and chord), the name given to the two-stringed lyre, the invention of which is ascribed to Mercury by Apollodorus, who gives us the following account:—" Mercury," says he, "walking on the banks of the Nile, happened to strike his foot against the shell of a tortoise, the flesh of which had head which army by the sun and nothing left of had been dried away by the sun, and nothing left of its contents but nerves. He was so pleased with the its contents but nerves. He was so pleased with the sound it produced, that he thence conceived the idea of a lyre, which he afterwards constructed in the form of a tortoise, and strung it with the dried sinews of animals."

Dick Brovest, dik, is a fund left by Mr. James Dick, of London, a native of Forres, in Morayshire, who amassed a considerable fortune in the Indies, and at his death, in 1828, bequeathed the bulk of it, amounting to upwards of £100,000, as a fund to be applied for the benefit of the parochial schoolmasters of the counties of Moray, Banff, and Aberdeen. This money has been of immense service, not only in increasing the comforts of an underpaid class of men, but in raising the standard of education. The teachers, before participating in the fund, are subjected to a very searching examination; and there is also a visitor appointed to inspect and report periodically upon the condition of their schools. The sum which each teacher receives is thus made to depend upon his qualifications and efficiency in teaching, and at present varies from about £20 to £40, the average being about £30. The sum annually distributed is about £4,000; but a number of teachers do not participate in it, from

not having passed the necessary examination.

DIGER, dik'-er (Gr. deka, ten), is a word used by old authors, signifying ten; as a dicker of skins or hides, —i.e., ten hides; a dicker of gloves, or ten pairs of

DICOTYLEDONES, di-ko-til-e'-dones (Gr. dis, two; kotuledon, a cavity), in Bot., one of the two great classes into which the phanerogamous or flowering plants are divided. It agrees with the Erogenæ of some botanists, and with the Exogens and Gymnogens of Lindley. (See BOTANY.) The name Dicotyledones is derived from the condition of the embryo prevailing throughout the vast majority of plants included in the class; but, as in all other natural groups, instances occur wherein the particular character which has suggested the name is absent. In these exceptional cases, however, the plants agree with the rest in other prominent characters, as the structure of the stem and the plan of the flower. The presence of a pair of cotyledons in the embryo must not, therefore, he regarded as an essential character of the Dicotyledones. though it is presented by most of the plants in this great natural group.

DICTAMNUS, dik-tam'-nus (from Dicte, a mountain of Crete, where it grew), in Bot., a gen. of plants belouging to the nat. ord. Rutacee, including two species, which are commonly cultivated in gardens for the sake 

DICTATOR, dik-tai'-tor (Lat.), the highest magistrate

## Dictionary

in the ancient Roman republic. The first dictator was appointed about the year 253 a.u.c., or 501 n.c. As the consuls possessed equal authority, and often differed in their opinions, jealousy frequently brought disunion into the government. In order to avoid these evils, the dictatorship was established. The dictator united in himself the power of the two consuls, and the authority of all the other magistrates, except that of the tribunes, ceased as soon as he was appointed. He was attended, both within and without the city, by twenty-four lictors, bearing fasces and axes. At first, the dictator was only taken from the patrician order, but in 556 B.C., Marcius Rutilus, a plebeian, was elected. The dictatorship could not lawfully be held longer than rine dictators in could not tawning to ned to loger than six months; but Syllis and Julius Casar were nominated perpetual dictators, the former in 81 B.C., and the latter after his victory at Pharsalus. The title of dictator was declined by Augustus, and was never assumed by the emperors of Rome. In Niebuhr's Roman History the office of dictator is traced back to the Latins, from whom, according to the historian, it was introduced into Rome.

DICTIONARY, dik'-shun-ā-re (modern Lat. dictiona-rium, from dictio, a saying), is a work which professes to give information on an entire subject, or an entire to give information on an entire subject, or an entire branch of a subject, under words or heads arranged in the order of the alphabet. Thus we have dictionaries of Art, Science, and Literature; of Law; of Medicine; of Anatomy and Physiology, &c. In a more limited sense a dictionary is a collection of the words in one or more languages, arranged in alphabetical order, with their significations; as, an English dictionary, au English and French dictionary. It is necessary for a dictionary that the subjects be arranged in alphabetical order, that some explanation or interpretation be attached to each term, and that it professes to go over the whole subject or field of knowledge which it takes up. Dictionaries may be divided into three classes, according as they take up words, facts, or things. Dictionaries of words are generally such as explain in alphabetical order the words composing any language, in the same language, or interpret them by the words of some other. Special dictionaries contain only the words used by single authors or classes of authors. A dicused by single authors or classes of authors. A dictionary usually, also, gives an explanation of phrases; for when it is confined to single words, it is properly only a vocabulary. The Greek term Lexicon is sometimes used as equivalent to dictionary. The term Thesaurus (treasury) is also sometimes used. A glossary (Lat. glossarium) is a dictionary of unusual terms. The ancient Greeks and Romans made use of glossaries of unusual words and phrases, but had no dictionaries of language in our sense of the term. In learning a of language in our sense of the term. In learning a foreign language they seem to have adopted the natural method of conversation. It was not till after the invention of printing, when a taste for the classic languages of antiquity began to prevail, that dictionaries of these languages came into use. The Latin Thesaurus of Robert Stephens made its appearance in 1831, and in 1852 the Greek Thesaurus of Harave 1531; and in 1572 the Greek Thesaurus of Henry 1531; and in 1572 the Greek Thesaurus of Henry Stephens was published. Among the most carefully-compiled dictionaries of modern languages are the "Vocabolario degli Academici della Crusca," of the Italian; and the "Dictionnaire de l'Académie Française," of the French. The Spaniards also possess a dictionary of considerable merit, cutitled "Diccionario de la Lengua Castellana," by the Royal Spanish Academy. In English, Johnson's dictionary, which made its first appearance in 1755, notwithstanding the defeate still replies as a standard work of its class. defects, still ranks as a standard work of its class. defects, still ranks as a standard work of its class. Dr. Richardson's dictionary, which first formed part of the "Encyclopedia Metropolitans," but was afterwards published separately, is rather critical and philosophical than practical, and adopts the principle of giving together all the words derived from the same root. It is particularly valuable for the numerous examples which it gives of the uses of the words.

## Die-sinking

dictionary is a want which has not yet been supplied. The first German dictionary of any note was that of Adelung, in 4 vols., Leipsic, 1774-30. A much more valuable work was that of Campe, "Deutsche Wörterbuch," 5 vols., Brunswick, 1807-11. Immeasurably surpassing it is the "Deutsche Wörterbuch" of the brothers Grimm, of which the first volume appeared in 1854, and which is still in course of publication. For those who wish a list as complete as possible of the dictionaries of all languages, we must refer to Vater's Litteratur der Grammatiken, Lexica und Wörtersammiungen aller Sprachen der Erde, 2nd ed., by Il. Jülg, Berlin, 1817. The second class of dictionaries—those of facts—comprehends dictionaries of History, Jülg, Berlin, 1817. The second class of dictionaries—those of facts—comprehends dictionaries of History, Biography, Geography, &c. They deal chiefly or exclusively with facts that exist, or have existed, or with events that have happened, or are supposed to have happened. They are frequently incorporated or combined with the third class, or dictionaries of things, which will more properly come to be noticed under the head of ENCXCLOPEDIAS.—Ref. English Cuclonedia. Cyclopadia,

DICTUM, dik'-tum (Lat., something said), is properly applied to the arbitrament or award of a judge, but is

applica to the motivament or award of a judge, for an frequently also used to denote a positive assertion.

Did notice, di-ddk-tik (Gr. didusko, I teach), significe speaking or writing in a manner adapted to teach or explain the nature of things. Hence didactic poetry has for its object the communicating of instruction in the form of poetry. In one sense, almost every kind of poetry may be said to be more or less didactic; more particularly, however, it is applied to those case in which the chief object of the poem is to communicate of Virgil, the "De Rerum Natura" of Lucretius, and the "Ars Poetica" of Horace. Though didaction poetry may sometimes attain an elevated and animated character, yet it cannot be denied that the more it becomes diductic, the less, of necessity, is it poetical; for the invention, freedom, and elevation of poetry must be in a great measure dropped. Didactic poetry must have been among the earliest forms of poetic composition, and there is scarcely a nation in which it not taken root; while at the same time there is hardly a subject, however prosaic, that has not found some one to give it a poetic dress. In didactic poems,

some one to give it a poetic cress. In didactic poems, generally, the information or instruction is accompanied with reflections, illustrations, &c.

DIDASCALIA, di-dis-kwi-le-a (Gr., instruction, information), a term in use among the Greeks, and also till recently among most of the nations of modern Europe. It was sometimes applied to the representation of denorstic nature. tion of dramatic pieces, but more particularly to a written addition, in which information is given of the authors and contents of the plays, of the time, place, and success of the representation, &c. Many old and success of the representation, &c. Many old authors have written didascalia, containing not merely theatrical information, but also critical notices of the

thearrean information, but also critical notices of the plays, giving an analysis of the plan and development, the beauties and defects of each.

DIDYMUM, did'-c-mc-um (Gr. didunos, twin), in Chem., a very rare metal, closely allied to cerium, and occurring with it in its ores. It forms one oxide, which has the properties of an earth.

DIE-SINKING, di-sink-ing (Fr. de, die; Sax. sincan, encan, to sink), the art of preparing a die or stamp by which an impression is produced on medals or pieces of which an impression is produced on medials of pieces of money, or any pattern or device on buttons and thin plates of metal, by means of great pressure. When a die is required for a coin or medal, the engraver takes a piece of soft steel of suitable dimensions, generally three or four inches in length, and about an inch greater in diameter than the coin required. On this he hollows out the exact form of the desired impression by cutting out the exact form of the deared impression by dutting away the steel by degrees, with small, well-tempered, case-hardened tools. As soon as this is done, the steel is hardened by being heated red-bot in a crucible with charcoal and oil, or bone-dust (see CASE-HARDEN-ING), and then plunged into cold water. When a great number of coins of one sort are required, the original examples which it gives of the uses of the words, and generally useful dictionary is that by Dr. N. Webster, of America, which has several times been reprinted in this country. Based upon it is the "Imperial Dictionary," by Dr. John Oglivie, which is a very useful and tolerably complete and accurate work. Walker's "Critical Pronouncing in the words. Walker's "Critical Pronouncing in the correct produced by the pronouncing in the first produced by being heated red-bot in a cruoble with charcoal and oil, or bone-dust (see Case-narden in the country). Based upon it is the "Imperial Dictionary," by Dr. John Oglivie, which is and accurate work. Walker's "Critical Pronouncing in relief, and is called the puncheon, and from which, when it has been hardened, other dies are produced by pressure exactly similar to the matrix, and in integlio,

#### Dies Ire

which are case-hardened in their turn before they are fit to transmit an impression to any metal used for money. The metal used for our coinage, whether gold, silver, copper, or bronze, is stamped in a cold and solid state; but medals and casts can also be produced by a method called casting ex clické, in which the metal is used in a solf state, and an impression may be obtained even from dies of wood or plaster. For this process an alloy is used, consisting of \$1 lead, \$1 tin, and \$5 bismuth, which fuses readily at the boiling-point, 212° Fahrenheit. When the metal is still soft, resembling paste in consistency, the die is placed unon it. and the paste in consistency, the die is placed upon it, and the impression produced by a smart blow from a mallet. The surface of the metal sets instantly, from coming into contact with that of the cold die, and thus readily retains the form that has been given to it. Copies of medals may be readily made in this way; but each medals may be readily made in this way; but each fince will be obtained in a separate piece, and these must be joined to give a representation of the coin in a complete form. A quantity of ornamental-work is produced in thin metal for gas-fittings, cornices, parts of cruet-stands, trays, &c., by means of a pair of dies, on one of which the pattern is formed in relief, and on the other in intaglio, the metal being placed between them, and brought into the desired shape by pressure. Dies are also made in metal for forming articles in gutta-percha and leather, and producing embossed figures on the cloth covers of books, as well as on cardboard, paper, &c.

DIES IER, di'es i'-re (Lat., day of wrath), is the name commonly given, from the opening words, to a celebrated Latin hymn, describing the final judgment of the world. It is characterized by remarkable force and beauty, combined with great smoothness of phyme,

and commences :-

Dies iræ, dies illa, Solvet sæelum in favilla, Teste David cum Sibvlla.

Quantus tremor est futurus. Quando Judex est venturus, Cuncta stricte discussurus!

Tuba mirum spargens sonum Per sepulchra regionum, Coget omnes aute thronum.

The authorship of this beautiful hymn has been ascribed to various persons; but it most probably proceeded from the pen of Thomas of Celano, a Franciscan monk, who died about the year 1255. In the 14th century it was admitted into the service of the Church, and made a part of the Requiem, or mass for the souls of the dead. Several alterations were then made in the text; but that is believed to be the original reading which is found engraved on a marble tablet in the church of St. Francis at Mantus. This hymn has been frequently translated into German, and has been done into English

translated into German, and has been done into English by Lord Macanlay, Lord Lindsay, and others.

Dier, di-et (Ger. reichtlag, Du. ryksdag, Dan. rigsdag), is derived from the Latin dies, 'a day,' and is properly the day of the empire. It is applied to the principal national assembly of various countries of Europe. Under the old German empire, the emperor summoned annually two regular diets, which met usually at Ratisbon, besides extraordinary ones on special any at hatsoon, besides extraordinary ones on special occasions. The emperor and the diet exercised all the prerogatives of sovereignty, levying taxes, enacting laws, declaring war, and making peace. The diet was composed of three chambers:—1. The chamber of Electors; 2, that of the Princes, which was divided the contractions of the princes, which was divided into two sections,—the spiritual and temporal,—the former being subdivided into the Swabian and Rhenish benches, each of which had one vote, and the latter into the Wetteravian, Swabian, Franconian, and Westphalian benches, each of which had also one vote; 3. the chamber of the Imperial Cities, divided into the Rhenish and Swabian benches. Each of the chambers Idensish and Swadian Denoices. Each of the chambers deliberated separately; but then the two first met together, and decided definitively on any proposition, which, when ratified by the emperor, became a decree of the empire. The emperor could refuse his ratification, but could not modify she decisions of the diet. The diet of the modern Germanic confederation is a meeting of plenipotentiaries, which is permanent, and assembles in the free city of Frankfort-on-the-

## Dietary, Military and Naval

Maine. The diet is constituted in two forms;—1. as a general assembly, called *Plenum*; and 2. as a minor council. The Plenum meets only when some organic change is to be introduced, or any affair relating to the whole confederation to be decided. Every member of the confederation has at least one vote, and several of the larger powers, as Austria and Prussia, have four; the larger powers, as Austria and Prussia, have four; making in all seventy votes. In making or altering fundamental laws, unanimity is required; but in other cases matters are decided by two-thirds of the number of votes. In the ordinary or federative diet, there are only seventeen votes, of which the eleven, principal states have one each, and the remaining twenty-seven only six among them. It brings forward and discusses propositions which are to be presented to the Plenum, where they are not debated, but simply decided by votes. It also executes the enactments of the Plenum, and disnatches the current husiness of the plenum, and disnatches the current husiness of the confederavotes. It also executes the enactments of the Figure and dispatches the current business of the confederation. It decides by a simple majority, and soven votes form a quorum. Austria presides in both diets, and has the casting vote in the smaller assembly. The deputies have the character of plenipotentiaries, are responsible only to their respective governments, and must therefore act according to the instructions of their own courts, and not after their own convictions. The diet of Hungary is composed of the king (the emperor of Austria) and the estates, the latter being divided into two chambers,—an upper and a lower. They consist of the higher clergy, the magnates, the two courts of appeal, and two representatives from each chapter, county, city, and privileged district. The diet of Switzerland is composed of the representatives of the cautons, and is held every two years, alternately at Zurich, Berne, and Lucerne. It manages such affairs of the constitution as are not within the jurisdiction of any of the separate states. Each canton has a vote in the diet.

DIETARY, MUITARY AND NAVAL, di-et-a-re (from r. diaita, manner of living), that which pertains to Gr. diaita, the prescribed rules for feeding among soldiers and sailors. In the British army the dietary is under the control of the commissariat department. During the Crimean war the necessity of reform in the distribution of food and daily necessaries became too painfully apparent. Since that time the whole arrangements have been put on a new footing. The commissariat is now a War-office depurtment, under a commissariat is now in chief. The cooking of provisions has also since that time become a commissary generaltime become a very important feature in the English military system. It was too palpably shown that military system. It was too palpably shown that cookery was but little understood by the British soldiers. Government sent out M. Soyer principally the principally the principally the principal to be principally the princi to give advice in regard to hospital cookery, and also to superintend the general military dietary. A com-mittee was appointed a few years ago to consider the subject of barrack economy, and they recommended that every large barrack should have a bakery with two ovens, where the men could learn to bake and make their own bread. They also advised that arrangements should be made by which the men might be enabled to bake their own meat, instead of eating it always boiled. Gradually these recommendations are being acted upon, and nearly all large burracks are provided with new and carefully-arranged stoves. The cooking arrangements at the new barracks at Aldershot are superior to any yet used in the English army. (See COMMISSABLAT, RATION.) In naval dietary two circumstances are taken into account in supplying provisions to ships in the royal navy ;--first, the ration or established allowance of certain articles; and second, the average ex-perience of the past with regard to others. Under the first head all rations are equal, from the first officer to the ordinary seaman; under the second head there are the ordinary seaman; under the second head there are wide differences: thus, fresh ment, preserved meat, lemon-juice, wine, &c., are considered as non-guaranteed by the crew, and can he given or withheld, as circumstances may occur. Naval dictary has changed from time to time in relation to the kind and quality of food supplied. The daily ration in 1844 was as follows:—biscuit 1 lb., salt neat \$1 lb., vegetables \$1 lb., sugar 1\frac{1}{2} oz., rum \$\frac{1}{2} \text{pint.} A small quantity of oatmeat and vinegar were also allowed every week. The cost of the naval dictary in 1844 was about £18 per man per annum. In 1847 tea and sugar were first introduced into the sailor's dietain lieu of rum; government has,

#### Dietetics

however, never tried to force the temperance system on the navy. In 1859 the dietary was made more liberal by the Admiralty, in order to increase the attractiveness of the navy; no country is now so liberal in its naval dietary as England. The dietary in emigrant ships is regulated by law, every ship being bound to possess certain kinds and quantities of provisions, according to the number of the passengers and the length of the voyage.

Dieterios, diet-et-iks (Gr. diaitetike), is that department of medical science which relates to the diet or ordinary food. (See Food.)

partment of medical science which relates to the diet or ordinary food. (See Food).

DIEU IT MON DROIT, dyu(r) ai mawn(g) drwaw (Fr., God and my right), the motto of the royal arms of England, first assumed by Richard I., to intimate that he held his sovereignty from God alone, and not in reassalage to any man. It seems to have subsequently been dropped, but was afterwards assumed by Edward III and was continued (except during the reign of III., and was continued (except during the reign of Elizabeth), without interruption, to the time of William III., who used the motto Je maintiendray, though the former was still retained upon the great seal. After him, Queen Anne used the motto Semper eadem, which had been used before by Elizabeth; but, since the time of Queen Anne, Dien et mon droit has continued to be the royal motto.

DIFFRENCE, dif'-fer-ens (Lat. differre, to carry from each other), in Log., is one of the predicables, and denotes that particular quality which distinguishes the subject under contemplation from all others, when looked at from the point of view in which we are regarding it. Logically, it is said to express the formal or distinguishing part of the essence of a species,—that which distinguishes it from every other species contained under the same genus. The having only three sides is the difference or distinguishing feature which separates triangles from squares, polygons, and every other species of figure contained under the common

genus rectilineal.

DIFFERENCES.—In Her., there are marks of differences of two classes; the former of which is used to distinguish different branches of the same family from each other and from the chief of the family, when the original bearer of the coat is dead; and the latter to distinguish the coat-armour of sons from the paternal cost, while the father is still alive. Marks of difference, properly so called, belonging to the first class, consist of the addition of a chief or border to the original cost; the eldest son bearing the paternal coat without any addition; the second son, the paternal coat within a plain border; the third bearing it within a border engrailed; the fourth, with a border invected; the fifth, within a border wavy, &c. Sometimes differences have been shown by assuming borders of different nave been snown by assuming orders of underent tinctures or metals, or by altering the colours and metals of the field and charges of the coat. Differences of the second class, properly called marks of cadency, consist of the addition of a certain figure to the paternal coat for each of the sons; these figures con-sisting of a label of three points for the eldest son, a crescent for the second, a mullet for the third, a martlet for the fourth, an annulet for the fifth, a flaux-do. is for the sixth a rose for the seventh a cross fleur-de-lis for the sixth, a rose for the seventh, a cross moline for the eighth, and a double quatrefoil for the ninth. When the father is dead, the marks of cadency ninth. When the father is dead, the marks or causing should be erased and the border substituted, as mentioned above. The princes of the blood royal bear the label only on the royal arms, and are distinguished by

label only on the royal arms, and are distinguished by bearing various emblems on the points of the label. The prince of Wales, however, bears a label argent simply, without any distinctive mark on the points. DIFFREENTIAL CALCULUS, dif-fer-en-shid (Lat. dif-fero, I move apart), a term applied to one of the most important branches of the higher mathematics. The object of the differential calculus is to find the ratios of the differences of variable magnitudes, on the supposition that these differences become infinitely small. In this study it is necessary to pay particular attention to the meaning of the terms infinitely and infinitely small. All magnitudes in mathematical reasoning are considered to be capable of augmentation and diminu-tion without limit. A quantity, therefore, can be conceived to be so great as to exceed any finite quantity fully conveyed to the bottom of the vessel, it will be of its own nature, or so small as to be less. In the found that, after the lapse of a few days, the wine will first case it is said to be infinite, and in the latter gradually diffuse itself into the water and the water

# Diffusion of Liquids

These magnitudes are of course infinitely small, imaginary, as in both cases quantities may be conceived either greater or smaller; so that an infinitely large quantity may be considered as nothing, or zero, and quantity may be considered as account, of serio, sun an infinitely small quantity as the same, when compared with one another. In the differential calculus, the infinitely small quantities which come under consideration are called differentials. The differential of a magnitude, or variable function, as it is called, is emiginitude, or variable induction, as it is called, is expressed by placing the letter d before the magnitude or function. Thus dx signifies the differential of the variable magnitude x. Formerly it was the custom to put a dot over the fluxion of a quantity, as it was then called. Thus x represented the fluxion of x. The use of the letter d was introduced by I calling when of the letter d was introduced by Leibnitz, who, con-temporary with Sir Isaac Newton, gave much attention to the subject. These two philosophers, independently of one another, studied the science of the differential calculus at the same time; but of late years the method of Leibnitz has almost exclusively prevailed, to the exclusion of the name, notation, and method of

Newton's fluxions, in such points as they differ.

DIFFRACTION OF THE RAYS OF LIGHT, dif-frak-shun (Lat. difractum), in Optics, the modification which light undergoes in passing very near the edges of any opaque body. It was first observed by Grimaldi, who noticed that when a ray of light was allowed to enter noticed that when a ray of light was allowed to enter a dark reom, the shadows cast from any opaque body were larger than if the light passed by it in straight lines, and that those shadows have three bands of coloured light parallel with them. At first this phenomenon was attributed to the refracting power of the atmosphere; but this theory was disproved by Newton, who treats of the subject in the last book of his Optics. He endeavoured to explain its occurrence through the general properties of light. It is now looked upon as identical with many phenomena connected with the undulatory theory of light, and is assigned to the inter-

ference of undulations.

DIFFUSION OF GASES, dif-fu'-thun (from Lat. dif-fundo, I pour ont hither and thither), in Chem.—If two vessels be filled with two different gases, and connected by a tube, it will be found that, after a certain lapse of time, an intimate and equal intermixture of then will take place. If, however, means be taken to measure the velocity with which they mix, it will be found that the lighter of the two diffuses itself much more rapidly into the heater than vice versa. This velocity of diffusion may be measured in the following manner:—If a glass tube, closed at one end with a porous plug of plaster of Paris, is filled with hydrogen, and plunged mouth downwards, the hydrogen will gradually press through the porous disphragm into the air, and the air will gradually supply its place. But it will be found that the hydrogen diffuses itself into the air much more rapidly than the air into it, causing the water to rise in the tube, contrary to the action of gravity. Mr. Graham and others, by a similar apparatus, have determined the exact rates of diffusion of all gases, which appear to be in accordance with a law that the relative diffusiveness of gases is unity divided by the square root of their density, taking air as the standard. The following are the velocities of diffusion of some of the more familiar gases:—

Hydrogen	3.83
Carburetted hydrogen	1 34
Oleflant gas	
Air	
Carbonic acid	0.81
Sulphurous acid	0.68

Diffusion of gases is a process that is continually going on around us. Were it not for this property, gases deleterious to animal and vegetable life would be constantly accumulating in poisonous masses, instead of being silently and harmlessly distributed through the atmosphere.—Ref. Graham's Philosophical Magazine,

DIFFUSION OF LIQUIDS, in Chem.—Liquids of different densities, like gases, gradually diffuse into each other when brought into contact. Thus, if a salt-jar be filled with water, and ryd wine be gradually and carefully conveyed to the bottom of the vessel, it will be

Digamma

into the wine, until the whole is uniformly mixed. By means of an apparatus of this kind Mr. Graham was enabled to calculate the different velocities of a large number of substances. These velocities vary in the most remarkable manner, sulphuric acid, for instance, diffusing into water with twenty-four times the velocity of albumen. Pursuing these experiments, Mr. Graham was at last able to classify all soluble substances with the velocities and in doing to the contract of the velocities and in doing to the contract of the velocities and in doing to the velocities and in doing the velocities and in the velocities are velocities and the velocities and the velocities are velocities and velocities are velocities are velocities and velocities are v stances according to their velocities, and in doing so stances according to their venerities, and in doing so he made the marvellous discovery that a disphragm covered with alayer of a solution of low velocity totally interrupted the passage of a solution of still lower power of diffusion through its mass. Carrying these ideas further, he has classified all soluble substances ander two heads,—colloids, or amorphous substances, similar to gelatine, which he takes as the substances, similar to gelatine, which he takes as the substances taking a crystalline form, and having a high diffusive velocity. These two classes seem to be divided naturally by other characteristics than velocity of diffusion. All crystallides were not not provided white called the characteristics than velocity of diffusion. onaracteristics than velocity of diffusion. All orystati-loids are more or less rapid, while colloids, such as starch, dextrin, albumen, &c., are insipid, and soluble with difficulty. Colloids offer but little resistance to the diffusion of crystalloids through their mass, while they are in a manner impervious to substances of their own class. On this property Mr. Graham has founded his system of dialysis, or the separation of the crystal-loid and colloid constituents of a liquid by the inter-vention of a colloid septum. (See Dialysis). Ano-ther curious property of colloids is their power of re-maining in solution until some disturbing influence suddenly reduces them to what Mr. Graham calls their pectous state. For instance, solution of ulmic acid may be preserved perfectly liquid for weeks in a scaled tube, but it is sure to become gelatinbus, and insoluble at last. The late discoveries of Mr. Graham in the crystalloid and colloid conditions of matter may be reckoned as amongst the most valuable of the day, and will increase the lustre of an already brilliant re The following table will give an idea of the relative diffusibility of crystalloids and colloids :-

Albumen .....49 Colloids. Caramel ......58.

(For a full account of Graham's experiments on diffu-

rot s tan account to grant the printers of this soon of liquids, see a paper by him in Philosophical Transactions for 1862, part I.)

DIGAMMA, di-gami-mā (Gr. dis, twice, and gamma, the letter gamma), was the name given to an old letter of the Greek alphabet, from its having the form of two gammas act one over the other, and resembling our F. It appears to have occupied the sixth place in . It appears to have occupied the sixth place in that alphabet, and to have had the sound of v. Much discussion, however, has been carried on regarding the nature and pronunciation of this letter, upon which we cannot enter, but must refer the curious to Kidd's cedition of Dawes Mincellanea Critica, and Ahren's De Graca Lingua Dialectis. The use of the digamma was most common in the Æolio dialect; but even from

was most common in the Asolic dislect; but even from this it disappeared at a very early period.

DIGEST, di'-jest' (Lat. digestus, put in order), is a name often applied to the Paudects of the civil or Roman law. It was compiled from the works of previous Roman jurists by Tribonian and others, at the command of the emperor Justinian, and was published

DIGESTER, di-jes'-ter (from Lat. digero, I distribute, dissolve), a strong iron or copper vessel, with a steamtight lid, furnished with a safety-valve, in which water and other fluids can be heated beyond their boilingpoints. This form of apparatus was first invented by Papin, and is in consequence frequently called Papin's digester.

DIGESTION, di-jest-tshun (Lat. digestio, from digero, I carry to different parts, or dissolve), in Physiol., is that process by which the food of animals is converted into chyme in the stomach, and prepared for being ultimately taken into the blood. The function or process of digestion is one of the principal of those that are directly concerned in the maintenance of life: and hence its proper performance is of the utmost importance to the individual; while depending, as it Digging

does, upon the healthy condition of a great number of organs, it is not to be wondered at that it is liable to disorders, and is productive of an endless variety of diseases under the general term indigestion. diseases under the general term indigestion. The principal processes connected with digestion are usually represented as,—(1) Mastication; (2) insalivation; (3) deglutition; (4) clymification, or the action of the stomach; (5) chylification, or the action of the intestines; (6) defæcation; and (7) the absorption of the chyle. The operation of mastication is a very important auxiliary to digestion; since the more the food is broken down and mixed with the saliva the more readily and completely will it be acted upon by the stomach. Imperfect mustication is a frequent cause of indigestion. During this process the salivary glands yield up their contents, by means of which the dry food is moistened and rendered more fit for deglutition. The third process is the act by which the food is transferred from the mouth to the stomach. (See DEGLUTITION.) The alimentary matter being propelled by the contractions of the osophagus into the cardiac extremity of the stomach, is there acted upon carriac extremity or the stomach, is there acted upon and dissolved by the gastric juice, which is secreted by glands lying in its inner or nucous coat. This process is assisted by the muscular contractions of the stomach, by means of which the mass is kept in motion until it is formed into chyme. When it has been sufficiently operated upon it operated upon, it passes through the pyloric opening into the duodenum. The pylorus possesses a peculiar sensibility, that prevents any matter from passing through it but such as has been properly converted into chyme. Recent investigations have shown that the changes which the food undergoes in the stomach are essentially chemical. (See Gastric Jutor.) The process of gastric digestion is very slow. It is more than an hour before the food suffers any apparent change; and the ordinary time required for the diges-tion of animal food is from three to four hours. The tion of animal rood is from three to four nours. The chyme having passed through the pylorus into the duodenum, becomes mixed with the biliary, pancreatic, and intestinal secretions. These juices, by their action upon the chyme, separate it into two portions,— one smilky fluid called chyle, the other the excrementatious portion. The bile seems to be of use principally in promoting the digestion of fatty matters, while the pancreatic juice serves mainly to convert starchy matters into sugar. Of the use of the intestinal juice ittle is known. The chyle attaches itself to those irregular circular folds of the mucous membrane of the small intestines, called the valvulæ conniventes, where it is absorbed by the lacteals. The large intestines also possess lacteals; so that, if any portion of the chyle should not have been absorbed in the small intestines, it is taken up in the large ones. pass gradually from the small to the great intestines, until they reach the rectum, where they are retained for some time and then discharged. The absorption of the chyle forms the last act in the process of digestion. It is, as we have already seen, taken up by the lacteals, and is by them conveyed to the mesenteric glands, where it is supposed to undergo some change. From thence it makes its way to the right side of the aorta, in the lumbar region, where it is finally discharged into an elongated pouch, called the receptaculum chylic From this pouch the thoracic duct conceys the chyle upwards to the left side of the neck, where it is poured into the left subclavian vein at its junction with the internal jugular, and, being thus mixed with venous blood, it is carried to the lungs and there converted into new and perfect arterial blood.

DIGESTION, in Chem., is heating a substance in a liquid, in order to extract some principle contained in it. It is distinguished from maceration by being

performed at a high temperature.

DIGESTIVE, di-jest'-iv, in Surg., is a term applied to such applications, ointments, poultices, and the like, as promote, or are believed to promote, healing or suppuration, when applied to a wound or ulcer. Though puration, when applied to a wound or ulcer. common formerly, the term is now little used.

DIGGING, dig-giag (Ang.-Sax.), the operation of moving, or stirring, or breaking up earth with a spade, pickare, or other sharp instrument. It is mostly performed in gardening, but in some situations, where the size of the inclosures is small, or where the power is insufficient for the cavy working of the

Dilatory

common or the subsoil, plough, cultivators prefer manual labour with the spade. Experience, too, has proved that the expense of deep-digging, or spade-busbandry, is not materially different from that of the subsoil plough. In gardening, the chief use in digging is to mix the soil by burying the surface and bringing what is below to the top. In private gardens digging is often much neglected; but commercial growers, who have to make the most of their ground, pay particular attention to the subject, and the result is seen in their superior productions. In ordinary digging, the spades used in the market gardens round London are 134 fitches long and 10 inches broad. Those used in private gardens are smaller,—Ref. Johnson's Furmers' private gardens are smaller .- Ref. Johnson's Furmers'

Encyclopedia.

Dierr, di'-jit (Lat. digitus, finger), a finger; a term employed in Arith. to denote one of the ten symbols or figures, 0, 1, 2, 3, &c. According to the original acceptation of the term, the first ten figures of any row were digits, but now, by common acceptation, the term is employed to denote the first ten figures used in the common acceptation, the term is employed to denote the first ten figures used in eckoning number; thus, 20 is a number of two digits. By astronomers the term digit is used to signify the twelfth part of the diameter of the sun or moon; thus, in speaking of eclipses, they say that it was of

seven or eight digits.

EXBECISES, dij'-it-al eks'-er-si-zes (Lat. DIGITAL digitus, a finger; Fr. exercice), in Practical Mus., are exercises employed for the purpose of rendering the fingers independent of each other. As the third finger is the weakest, it is very necessary for all who practise the pianoforte, &c., to cultivate its volition, and strengthen it by exercises adapted for that purpose.

Desiralis, dij-dt-dt-dts (Lat. digitus, s finger), in

Desiralis, dij-d-ai-dis (Lat. digidus, a finger), in Bot., a gen. of plants belonging to the nat. ord. Scrophulariacea. The most important species is D. purpurea, the purple foxglove, one of the handsomest of our indigenous plants. It is a biennial, blossoming during the months of June and July, and is found on hedge-banks and/the sides of hills, in dry, gravelly, or sandy soil. The flowers are somewhat bell-shaped, and their remote resemblance to the fingers of a glove suggested the generic name. They are beautifully marked on the inside with purple blotches. The foxglove sometimes grows to a great height: one specimen rathered times grows to a great height; one specimen gathered near Tintern Abbey, measured 7 ft. 9 in., the spike of flowers was 4ft. 10 in. in length, and the number of flowers thereon 311. A variety commonly met with in gardens has white flowers epotted with different shades of cream-colour and pearl. The wild foxglove is a most important medicinal plant. The leaves only are officinal in our pharmacopesias; but the seeds and roots pos in our pharmacopenas; but the secus and roots pos-sess similar properties. Digitalis is a duretic, and greatly resembles tobacco in many of its properties. It is employed to reduce the action of the heart in diseases of that organ, in fever, and in inflammations. It is prescribed as a diuretic in dropsies of all kinds, but is most useful in those associated with a debilitated and generally diseased state of the constitution. It is a violent poison, and great care is requisite in pre-scribing it, as its use, even in small doses, has led to fatal results: for it accumulates in the system. active principle of forglove is termed digitaline.

DIGITIGRADA, dij'.pit-e-prai'.da (Lat. dijitus, a finger; gradior, I walk), in Cuvier's zoological system, a tribe of carnivorous animals distinguished by walking upon the toes, the heel being always raised from the ground. Those animals which place the heel or the sole of the foot on the ground belong to the tribe Plantigrada. Some of the most carnivorous mammalia belong to the digitigrada. The feline and canine fami-

belong to the digingrada. The leads and canno namines, hymnes, civets, &c., are all included in it. The Wessel fam. (Mustelidæ) appears to form a connecting fink between the digitigrada and the plantigrada.

DIGNITAEN, digi-ne-tā-re (Lat. dignas, worthy), in coclesiastical matters is one who holds cathedral or other preferment, to which jurisdiction is annexed, which is a consequence over more private of giving him some pre-eminence over mere priests or canons. The dignitaries in English cathedrals are, for the most part, the dean, precentor, chancellor, treasurer, and archdeacon; but in cathedrals of the new

surer, and arendeacon; but in enthedrais of the new foundation, the only dignitary is the dean.

Dignira, dig-no-te (Lat. dignus), denotes nobleness, or elevation of mind, consisting in a high sense of justice, truth, and propriety, with an abhorrence of all

mean and sinful acts. It is also applied to the titles of honour and authority among men; and these, in this country, are usually divided into superior and inferior, the former comprehending dukes, marquises, and the like; the latter, baronets, knights, &c. They were originally annexed to the possession of certain estates in land, and created by a grant of these estates; and although they have now become little more than personal distinctions, they are still classed under the head of real property. Having thus, in theory at least, re-lation to land, they may be entailed by the crown within the statute De Donis. No temporal dignity of any foreign nation can give a man a higher title than that of esquire. Dignity, in Oratory, is one of the three parts of elecution; consisting in the right use of tropes and floures.

and ngures.
DIGBAPH, di'-gröf (Gr. dis, twice, and graphe, I write), in Gram, is a union of two vowels of which only one is sounded; as in head, breath. It differs from a diphthong, which also consists of two vowels, in the sound produced in the latter case being different from the of cibles of the graph to the grant that from that of either of the vowels taken separately.

Dioression, di-gres'-shun (Lat. digressio), denotes literally a stepping out of the way or road; and hence, in literature, a departure or wandering from the main subject under consideration. Digressions may some-times be introduced with great effect; but they ought not to be had recourse to without sufficient reason, and should never be too frequent nor too long. Frequent digressions are a sure mark of an unskilful speaker or writer. Where a subject is heavy and dry, an occasional digression may serve to relieve the at-tention, and throw additional light upon it.

DIKE. (See DYKE.)

DILAPIDATION, dil-ap'-e-dai'-shun (Lat. di, and lapis, a stone), in ecclesiastical matters, is the suffering the edifices of a benefice to go to decay, and neglecting to repair them, and is also applied to the committing, or suffering to be committed, any wilful waste upon the glebe, woods, or other inheritance of the church. Dilapidations are therefore either permissive (arising from neglect) or voluntary (occasioned by some wilful act). By the Injunctions of Edward VI., it is required that the proprietors, parsons, vicars, and clerks, having churches, chapels, or mansions, shall yearly bestow upon the same mansions or chancels of their churches, upon the same mansions or chancels of their churchers, being in decay, the fifth part of their benefices till they be fully repaired; and the same being thus repaired, they shall always keep and maintain in good estate; for the revenue of the clergy is given not only as a provision for the clergyman, but also for his suitable residence. Dilapidations may be sued for in the spiritual courts; but it is most usual to do so by action at common law. The action may be brought by the successor against the predecessor, if living; or, if dead, against his executors; and against an alienee, if made over to him to defeat the remedy for dilapidations.

DILARATION, dil-a-tai-shun (Lat. dilatatio), is the expansion or enlarging of bodies after a state of contraction or compression. It differs from extension, as the latter is properly applied only to lines and surfaces, the former to bodies that spread open or enlarge in all directions.

DILATORY, dil'-a-tor-e (Lat. dilatio), denotes literally a delaying or putting off, and is applied, in Law, to certain pleas which are put in merely to delay the suit by questioning the propriety of the proceeding rather than by denving the injury. They are either pleus to the jurisdiction, showing that by reason of some matter there is stated, the case is not within the jurisdiction of the court; or pleas in suspension, showing some tion of the court; or pleas in suspension, showing some matter of temporary incapacity to proceed with the suit; or pleas in abutement, showing some matter for abatement, or quashing the declaration. These pleas must be verified by alfidavit, or evidence produced in the court to induce a belief in their truth; and in general they are not allowable after a plea in bar. The effect of a dilatory plea is that, if successful, it defeats the particular action, leaving the plaintiff at liberty to commence another in a better form, if the cases should be such as to admit of an amendment of cuse should be such as to admit of an amendment of that description. In criminal cases, a plea in abatement, or dilatory plea, is founded on some matter of fact extraneous to the indictment, tending to show that it is defective in point of form.

#### Dilemma

DILEMMA, dil-em'-ma (Gr. dis, twice, and lemma, an assumption,—a twofold assumption), in Log., is a species of argument in the form of a complex conditional syllogism. It is defined to be a redundant hypothetic syllogism, in which the hypothetical premiss consists of an antecedent or condition dependent on the several members of a distributive or disjunctive consequent. This argument was called by the Romans to Syllogismus corrupts. Whence our phrase of the Syllogismus cornutus; whence our phrase of placing one on or between the horns of a dilemma." It is used to prove the absurdity or falsehood of some assertion. A dilemma must be so framed that one of the alternatives must be admitted; and each alterna-tive must exactly apply. It ought also to be incapable of being retorted. When an affirmative is proved, the argument is said to be constructive; when a negative, it is called destructive. Of the constructive dilemma it is called destructive. Of the constitueive diaminisher or two sorts,—the simple, which concludes categorically, and the complex, which has a disjunctive conclusion. There is only one kind of destructive dilemma. The Greek dialecticians prided themselves on exhibiting dilemmas which they alleged to be insoluble. Some of these examples were constructed with great dexterify, and the discovery of the fallacy is by no means easy. One of the most famous of them, known as the "sophism of Euathlus," is as follows:—Euathlus had received lessons from Protagoras the rhetorician, on condition that the fee should be paid when the pupil gained his first cause. Euathlus delaying to undertake any cause, Protagoras sues him, and argues in this way: "If I am successful, you must pay me in virtue of the sentence; if unsuccessful, you mist pay me in terms of our agreement, as then you will have gained your first cause." The pupil retorts: "If I am successful, I am free by the sentence; if unsuccessful, I am free by the agreement."

DILETTANTE, dil-e-tan'-te (Ital., pl. dilettanti), is an admirer or lover of the fine arts, and is sometimes applied, by way of reproach, to one whose knowledge is mere affectation or pretence.

DILETTANTI SOCIETY, is a society of noblemen and gentlemen, formed in London in the earlier half of last century, and which has done much to foster the study of antique art in England. In 1764 it fitted out an expedition to Greece, for the purpose of collecting details and drawings of sacient monuments, the result of which was published under the title of "Ionian Antiquities," in 1769. They have since fitted "Jonan Antiquities," in 1769. They have since intead out several other expeditions, and given their results to the world in the same way. They have also issued "Specimens of Ancient Sculpture,—Egyptian, Etruscan, Groek, and Roman," selected from different collections in Great Britain, in 2 vols., London, 1809-35. The last work published by them is entitled, "Portfolio of Grock Architecture, or Drawing-book of Dilettanti,"

DILIGENCE, dil'-e-jens (Lat. diligentia, from diligo, I love carnestly), denotes generally a steady applica-tion of the mind or body to business of any kind; also tion of the mind or body to business of any kind; also care, attention, heedfulness. The law recognizes only three kinds of diligence,—(1) Common or ordinary diligence, which men in general exert with regard to their own concerns; (2) extraordinary diligence, or that care which very prudent persons take of their own affairs; and (3) low or slight diligence, such as persons of little or no prudence take of their own matters. In the law of Scotland diligence is also applied to the variant issued by the courts for accounting the to the warrants issued by the courts for enforcing the attendance of witnesses, or compelling the production It also denotes that process of law by which a creditor attaches the person, lands, or effects of his debtor, either on execution or in security for his debt. Dilizences are either real or personal,—real when applicable to real or heritable rights, and personal when for the purpose of securing the person of the

when for the purpose of securing the person of the debtor or his personal estate.

DILICENCE (Fr.), a heavy French travelling-coach, drawn by four horses. Before the introduction of railways, the diligence was much used in all parts of France. It is divided into three compartments,—the coupé, or front, holding three travellers; the intérieur, holding six; and the rotonde, entered from behind, holding eight. The driver's high seat in front is called the banquotte; and the rest of the passengers are huddled indiscriminately among the lugrage or under huddled indiscriminately among the luggage or under

### Diminutive

the tarpaulin which covers it. In general, a diligence weighs about five tons, and goes at the rate of six miles an hour.

DILL. (See ANETRUM.)

DILL. (See ANETRUM.)
DILLLENIACEE, dil-lene-ad'-sees (after the botanist Dillenius), in Bot., the Dillenius fam., a nat. ord. of dicotyledonous plants, in the sub-class Thalamillore, consisting of trees, shrubs, and a few herbs, having the following marks of distinction:—Leaves usually alternate, and, except in rare cases, without stipules: sepals and potals, five of each, hypogynous, the former persistent in two rows, the latter with an imbricated astivation: carpels more or less distinct; seeds arilestivation; carpels more or less distinct; seeds aril-late; albumen fleshy, homogeneous. The order inlate; albumen fleshy, homogeneous. The order in-cludes between 20 and 30 genera, and about 200 known cludes between 20 and 30 genera, and about 200 known species, occurring chiefly in Australia, India, and equinoctial America. They have astringent properties, and many are used for tanning and as vulneraries. The young calyces of some species of the typical genus Dillenia have an acid taste, and are employed to flavour curries in some parts of India. Many species of this genus grow to a large size, and form hard durable timber. Those of India are generally remarkable for fine evergreen foliage and very beautiful flowers. They are sometimes cultivated as stove or greenhouse plants are sometimes cultivated as stove or greenhouse plants

in this country.

DILLESK. (See RHODOMENIA.)

DILUENTS, dil'-u-ents (Lat. dilno, I wash away). Med., are liquids administered to increase the fluidity of the blood, and render certain of the secretions and exerctions less viscid. They likewise promote the operation of more active medicines, especially ape-rients and directics. Water is the simplest and frequently the best diluent; or it may be made more agreeable by the addition of acid or other substances, or is the form of tosst-and water. Gruel, infusion of tea, mutton and chicken broth, beef-tea, and such-like, come under this designation. Diluents are of great use in allaying the thirst of patients affected with fover or other inflammatory complaints, and are often very useful in subduing the more violent symptoms of the disease, and relieving the system by means of perspiration. The excessive use of fluids at meals, however, is hurtful to digestion.

DILUVIUM, di-lu'-re-um (Lat. die, asunder; luere, to wash), in Geol., a term applied to accumulations of gravel, sand, or stones, which are referred to the extraordinary action of water, the term alluvium implying the ordinary operations of water. At one time geologists merely used the word diluvium to distinguish accumulations supposed to have been formed during the Noschian deluge; but we now employ it as a common name for all masses which have apparently been pro-

duced by powerful aqueous agency.

DIMENSION, dim'-en-shun (Lat. dimensio), in Geom., signifies the extent of anything. A line, whether straight or curved, has only one dimension,—length; a surface has two dimensions,—length and breadth; while a solid has three,—length, breadth, and thickness. All forms of extension can be determined by these three dimensions. In Alg., the term dimension is applied to the number of true factors to a term, and is used very much in the same sense as degree; thus, x², xy, are of two dimensions; x², x²y, xyz, &c., are of three dimensions. An equation is generally said to be of as many dimensions as there are units in the index of the

highest power of the unknown quantity.

DIMINISHED, dim-in'-ishd (from Lat. di, and minuo, I make less). - In Mus., when an interval, by the application of a sharp or natural to the lower tone, or of a flat or natural to the upper, becomes contracted within its natural space or compass, it is said to be diminished: thus, by raising a minor seventh a minor semitone higher, a diminished seventh is produced. DIMINUTION, dimini-u'-shun (Lat. diminutio).—This term in Mus. implies the imitation of, or reply to, any given subject in rota of helf the leavel or value of

given subject in notes of half the length or value of those of the subject itself. For instance, a theme ex-pressed in minims and crotchets, and taken up in crotchets and quavers, would be said to be answered in diminution.

DIMINITIVE, dim-in'-z-tiv (Lat. diminutioum, from diminuo, I lessen), in Gram., is applied to a word whose signification is lessened or diminished by some change effected upon its form. Though diminutives are chiefly

#### Dimissory Letters

confined to substantives, yet we occasionally find them among adjectives, pronouns, and even verbs. The diminutive does not always express littleness or smalldiminutive does not always express littleness or small-ness, but sometimes, also, tenderness, affection, con-tempt, &c. They are usually formed by the addition of a syllable sit the end of a word. There is, perhaps, no language without diminutives; certainly, they are very common in most. Generally, they will be found to be most common in the language of a people of lively and affectionate manners, and prevail most in the friendly and familiar intercourse of the common people. The Italian language, particularly the Tuscan dialect, is especially rich in diminutives. The Spanish, Portraguese. French, and German languages likewise Portuguese, French, and German languages likewise abound with them. The old Scotch dialect is very rich in diminuitives, and there we sometimes find, as in the Italian, double diminutives; as, horsie, a little horse;

horsikie, a very little horse.

DIMISSONY LETTENS, dim'-is-sur-re, in the early Christian Church were, at first, letters granted to Christians on their removal from one place-to another; but, afterwards, the name came to be more strictly applied to letters granted to the clergy when they were to remove from their own diocese and settle in another, "No clergyman, of whatever degree," says the council of Trullo, "shall be entertained in sucther church of Trullo, "shall be entertained in another ch without the dimissory letters of his own bishop." the Church of England, dimissory letters are such as are given by a bishop to a candidate for holy orders, having a title in his diocese, directed to some other bishop, and giving leave for the bearer to be ordained by him. Persons inferior to bishops cannot, in ordinary

ses, grant these letters.

DINITY, dim'e-te (Du. diemit), a stout cotton cloth of a thick texture, generally striped, or otherwise ornamented in the loom. It is mostly white; but variogated dimities are frequently made, the pattern and the ground being of different colours. The figure or stripe is raised on one side and lowered on the other, so that the two sides present reversed patterns. Dimity is chiefly used for articles of female dress, and for bedfurniture or window-curtains.

DIMORPHISM, di-mor'-fizm (Gr. dis, twice; morphe, form), in Chem., the property possessed by certain bodies of assuming crystalline forms which cannot be derived from each other. Instances of this occur in the case of sulphur, which crystallizes as oblique prisms and as octahedra, according as it is crystallized by heat or from the solution in bisulphide of carbon.

DINGO, ding'-go (Canis Dingo), the native dog of Australia, regarded by some naturalists as a distinct species, but more generally as the descendant of a race once domesticated, and returned to its wild state. It is found in Australia both in a wild and tamed state; the tame dingo being about the size of our familiar sheep-dog, and the wild one somewhat larger. The latter has a large head, with a fuller muzzle than the sheep-dog; ears short and erect; tail bushy; colour tawny. It does not bark, and is very destructive to the sheep of the colonists; not so much on account of the amount of mest required for the satisfaction of its hunger, as from its savage habit of continuing to strangle as many sheep as its strength will allow before

at squats down to pick a bit of one. DINORNIS, di-nor-nis (Gr. deinos, wonderful or terrible; ornis, a bird), a gen. of large birds of the tribe Brevipennes. No species of the dinornis now exists, Brevipennes. No species of the dinornis now exists, but many bones belonging to birds of this class have been found in New Zealand, not only in the most recent deposits, but in the sand by the sea-shore, in caves, in swamps, in the soil of forests and in riverbeds. Among the natives there are many traditional reports about these birds, which were called most. Other large birds, such as the palapteryx and the aptornis, are also spoken of by them. It would appear that the dinornis became extinct at the end of the 17th or the beginning of the 18th century. According to the trabeginning of the 18th century. According to the tra-ditions of the natives, these birds must have had brilliantly-coloured plumage, and their flesh was a delicate food. For these two reasons they were objects stupid, anable to fly, and living in the mountains or in the depths of forests, feeding entirely on vegetable food. The bones of the diarraps have been closely was originally applied, under Constantine the Great,

#### Diocese

examined by comparative anatomists, and the descrip-tion of the natives coincides with the inferences drawn. The dinornia must have been considerably larger than any bird now existing; some of the bones found are twice as large as those of the estrich. The body must have been very bulky, and somewhat similar to that of the extinct dodo. The Dinornis giganteus must have been nearly eleven feet high. The bones of the legs are massive and semestably solid in structure. The are massive, and remarkably solid in structure. The num-ber of bones of the dinornis that have been found is very great. Several species have been recognized, and some skeletons have been nearly completely restored. The first bone examined by a naturalist was a leg-bone, and the naturalist was Professor Owen. From that bone alone he placed the dinorms in its correct place in the system of nature.

DINOSAURIA, di-no-saw-re-a (Gr. deinos, wonderful or terrible; autros, a lizard), a term applied to distinguish an order of extinct lizards found as fossils in the lias, colite, and wealden formations. There, are, however, no traces of them in the lower cretaceous strata. dinosauria were enormous reptiles of the lizard class, which approached nearer to the mammal type than any other of their order. Four powerful limbs supported their bodies, and the sacrum was composed of five vertebræ analgamated. The Mcgalosaurus, the Iguanodon, and the Hylmosaurus are the principal gen. of

the order.

DINOTHERIUM, di-no-the'-re-um (Gr. deinos, wonderful or terrible; therion, a wild beast), an extinct

DINOTHERIUM (RESTORED).

animal, whose cranial bones are found in the miocene formations of Germany, France, &c. Like the elephant.

remarkable anima Was provided with a pair of formidable tusks, which downwards from the lower It was juw. also provided on each side of its jaws with five double-ridged grind-ers. From the largeness of the nasal cavity, it supposed that the animal had a trunk like the elephant. As none of the body or limb bones of the dinotherium have been found, its true

# Diodon

to those larger civil divisions of the empire, each of which was under a prefect, and comprised several pro-vinces, which were under rectors. The government of the Church was adapted to this division, and each dio-cese was under the spiritual superintendence of an cese was under the spiritual superintendence of an archbishop, the term parish being applied to the charge of a bishop. Now the term diocese is equivalent to bishopric, and denotes the district over which the authority of a bishop extends. (See Bishopric.)

Diopon, di-o-don (Gr. dis, twice; cdous, tooth), a Linnæn gen. of fishes, now giving its name to a fam.—Diodontidæ. These fishes are about two feet in length,

of a nearly spherical form, and possess the pow inflating or contracting themselves at pleasure. When their stomachs are thus distended with air, there are displayed over the entire surface numerous spines, as though to protect its now somewhat unwieldy body from attack. It is, doubfless, this latter circumstance that has procured for the fish the titles of sex-porcupine and globe-fish. When inflated, the globe-fish is in-capable of swimming, but floats with the stream. They

capable of swimming, but noats with the stream. They are found in warm seas. The sun-fish is of this family.

DIONEA, di-o-ne'-a (from Dioni, one of the names of Venus), in Bott, a gen. of plants belonging to the nat. ord. Droseracea. The only species known is D. muscipula, a native of North America. This plant affords a remarkable instance of vegetable irritability. The leaf is two-lobed, and each lobe is furnished on its upper surface with three stiff hairs, which, on being touched have no investor way other charge the two belows. by an insect or any other object, cause the two halves to collapse and inclose the object. This plant, which is commonly known as Venus's fly-trap, is sometimes cultivated in our stoves.

Diorsis, di-op'-sis, a gen. of dipterous insects, remarkable for the length of the pedicles on which the eyes are situated. On this account it is likewise termed the telescope-fly. All the species are found in warm parts of the old world.

Diorraics, di-op'-triks (Gr. dioptrikes).—That por-tion of geometrical optics which treats of the passage of rays of light from one medium to another of a dif-

breath kind. (See Repraction, Ortics.)

Diorama, dia-ram'-i (Gr. dia, through; orac, I see), a method of painting and scenic exhibition invented by two French artists, Daguerre and Bouton. vented by two renear artists, Dagaerre and Bouton.
It does not possess all the advantages of a panorams, but produces a far greater degree of optical delusion. The peculiar effects of the diorams arise more particularly from the contrivances employed in exhibiting the painting. In the first place the picture is viewed through a proscenium; the room in which the spectators are is almost in darkness; and the light, which is admitted through coloured glass, falls upon the picture alone. It is principally used to illustrate architectural and interior views. By means of slides and shutters the light can be increased or diminished at will, and hence very pleasant effects can be represented; such as the ordinary change from daylight to sunshine, and from sunshine to cloudy weather or twilight. The from sunshine to cloudy weather or twilight. The diorams was first exhibited in Paris in 1822, and in London in 1823. It was at first very popular, a large building being creeted for its exhibition in Regent's Park. At first successful, it soon became unpopular, and the building is now used as a Baptist chapel

DIOSCORRA, di-os-kor'-e-ŭ, in Bot., the typical gen. of the nat. ord. Dioscoreaceæ. Various species, as D. alata, satica, and aculeata, produce the tubers called yams, which, when boiled, are esten in tropical countries as the potato is eaten in Europe. The Chinese yam is now cultivated in this country, and is

much esteemed by many as an esculent.

DIOSCOREACEE, di-os-kor-e-ai'-se-e, in Bot., the Yam family, a nat. ord. of monocotyledonous plants in the sub-class Dictyogenæ, consisting of shrubby plants with twining stems rising from tuberous root-stocks, with twining stems rising from tuberous root-stocks, or tubers placed above or under the ground, and having net-reined leaves, and small-spiked bractested flowers. They are natives chiefly of tropical countries, a few only being found in temperate regions. They are generally characterized by great acridity, though farinaccous matter adapted for food exists in the tubers of many species. (See Dissours, Tamus, Tartudi-Raria.) MARTA.

DIONNER, di-oz'-me-e (Gr. dios, divine; osme, smell). in Bot., a sub-ord. of the Rutacea (which see).

# Diphthone

DIOSPYROS, di-os'-pi-ros, imBot., a gen. of dicotyledonous trees, belonging to the nat. ord. Ebenacee. Many of the species have hard and dark-coloured heart-woods which constitute the different kinds of chony; thus, which constitute the different kinds of ebony; thus, D. Ebenum furnishes Mauritius ebony; D. melanozylon, a native of the Coromandel coast, the sort commonic known as black ebony; and D. Ebenuster, the basisard ebony of Ceylon. The beautifully variegated furniture—wood called Coromandel or Calamander wood, is obtained from D. kirsutu, and is brought to Europe from Ceylon. Other species also yield valuable timber. The fruit of D. Kaki is eaten in China. and is hown in the latter country as the and Japan, and is known in the latter country as the keg-fig. The fruit of D. wrginiana, a native of the United States, is sweet and edible when quite ripe, but very austere before then; hence it is frequently employed medicinally in its unripe state as an astringent. Dir, dip (Ang. Sax), in Min., a miner's and geologist's term for the direction of any mineral vein or stratum in relation to the horizon.

DIP, in Geol., the technical term for the angle at strata slope downwards into the earth. angle is messured from the plane of the horizon, and may be readily ascertained by the common spirit-level and plummet, or, as is usual among geologists, by a small pocket instrument called the chinometer (which see). To describe the opposite of dip, the term rise is used; and, as every bed that dips in one direction. must necessarily rise in another, either term may be used according to the position of the observer. For instance, a bed of coal which is spoken of by those on the surface as dipping to the south, would be described by the miners in the pit as rising to the north. The place where each bed rises to the surface of the ground place where each bed rises to the surface of the ground is called its outcrop or basset. Miners say that such and such beds "crop out" to the surface, and speak of their "basset edges." The line at right angles to the dip, that is, the line of outcrop of a bed along a level surface, is called its strike, a term introduced from the German by Professor Sedgwick. On geograph of the strike at the strike at the surface is called its strike, a term introduced from the German by Professor Sedgwick. logical maps the direction of the dip is generally indicated by an arrow, and the line of outerop, or strike of a stratum, by a bold line.

DIPHTHERIA, or DIPHTHERITIS, dif-the'-re-ë (Frdiphtherite, from Gr. diphthera, a skin or membrane),
is a very malignant and fatal disease of the throat,
which has recently made its appearance, and differs which has recently made its appearance, and unterser-from all other forms of sore throat previously known. It was first observed and described by M. Bretonneau, of Tours, in France, where it prevailed as an epidemic in 1818. It subsequently broke out in other French towns, and in 1857 it made its appearance in England, where it has since been, unfortunately, by no means rare, and has already caused a large amount of mortality. It is characterized by a peculiar inflammation of the mucous membrane of the throat, or pharyng, accompanied by the production of a false membrane. At first this membrane appears in the form of a white spot on the pharynx or tonsils, from which it gradually extends forwards to the soft palate and into the nos-trils, and backwards into the esophagus, sometimes into the larynx, but seldom into the traches, producing at length suffocation. It is usually accompanied by a feetid discharge from the nose and mouth, and hamorrhage frequently occurs. There is usually, also, a low and dangerous form of fever, with great depression of spirits and rapid decrease of the patient's strength, which is still further accelerated by his inability to take food. Various modes of treatment have been recommended. The patient's strength is to be supported by means of tonics and stimulants. Quining is generally recommended; and in most cases wino may be given with advantage. In the local treatment of the throat, nitrate of silver and chlorine are used. There can be little doubt that this disease is owing, in some measure, to the neglect of sanitary measures, and it is generally believed to be contagious, though some medical men deny both of these statements.

some medical men deny both of these statements.
DIPHTHONG, diff-thong (Gr. diphthogges, a double sound), in Gram, is a double vowel, or two vowels pronounced together or in rapid succession, so as to make only one syllable. Diphthongs, with relation to night, are distinguished from those with reference to sound: as an instance of the former, we have mouse; of the latter, mind. Many double vowels, however,

are not real diphthongs, because the sound of only one of the vowels is heard; as in bread, field.

of the vowels is heard; as in bread, field.
DIPLOMA, dip-lot-ma (Gr. from diplos, double), originally denoted any charter, letter, or other composition, written on parchment and folded. Afterwards it came to be applied to a letter or writing of a sovereign, conferring some title or dignity, or granting some privilege or immunity. The term is now commonly applied to a letter or instrument duly signed and given by a university or other learned accient. and given by a university or other learned society, in proof of the holder having a certain degree, or licensing him to practise a certain art.

Diffomacy, dip-lo'-md-se (Gr. diploma), is the art of conducting the official intercourse of separate states,

and particularly of negotiating treaties. The term is of recent origin, having only come into general use since the beginning of the present century, and is not to be found in Johnson's Dictionary. The art itself to be found in Johnson's Dictionary. The art tises is very ancient, and must have originated when people began to form themselves into distinct nations. In the earliest periods of history we read of heralds or messengers employed in carrying messages from one king or state to another, though regular and permanent embassics at foreign courts do not seem to have been maintained by any nation pre-vious to the 16th century. The subject has usually been treated under the head of Law of Nations; but in reality the two are quite distinct. The diplomatist requires undoubtedly to be sequainted with international law, and to observe its general conditions; but otherwise his sphere of operations is distinct and independent of it. Besides attending to the larger operations connected with treaties or alliances, the diplomatist has to keep a vigilant eye on the minor details of international law, to eee that these are equitably administered; in which seuse he is like a "law-agent, whose duty it is to see that his client receives justice at the hands of other nations under this code." It is, perhaps, worthy of notice that the term is frequently perhaps, worthy of notice that the term is requestly used in ordinary conversation to denote a certain degree of underhand cunning; and conduct which is wily and subtle, without being directly false or fraudulent, is styled diplomatic. It is generally in weak states that the science of diplomacy has flourished most. It owes its first marked development as a science to the Italian republics, who, exposed as they were to the attacks of great military monarchies, cultivated the attacks of great military monarchies, enliviated diplomacy with peculiar care. Their politicians, conspicuous among whom was Machiavelli, became celebrated for their unrivalled skill in the science; and it was long the practice of the greater states of Europe to employ Italians in negotiation, on account of their supposed peculiar aptitude for the subtleties of the profession. Italian diplomacy was in general profound, cautious, and unserupulous. It occupied itself much in forming combinations and alliances, and sometimes did not disdain to bribe, steal, forge, or even to murder. in order to accomplish its forge, or even to murder, in order to accomplish its objects. The origin of modern diplomacy is usually traced to the reign of Henry IV. of France (1599-1610), a monarch who was all his life surrounded by singularly delicate and difficult complications, and who was privileged to have about him remarkably able states men and negotiators, pre-eminent among whom was the famous Sully. Cardinal Richelieu (1624-42) con-tinued the foreign policy of France on the method of Henry IV., and is generally regarded as the founder of the present system of maintaining permanent legations at foreign courts. It was during his administra-tion that French began to supersede Latin as the language of diplomacy in Europe. Diplomacy greatly enlarged its field of action in the 17th century, and the ambitious and warlike policy of Louis XIV. exercised a marked influence upon the character of the diplomacy of his times. Artifices unknown to primitive

greatly extended. This extension of commerce, par-ticularly to distant parts, as America, Africa, and the West Indies, led to improvements and a remodelling of one branch of the diplomatic service,—the consular. The French revolution and the long series of wars that succeeded it wrought a great change in the character of diplomacy, by raising up gigantic combinations against Napoleon and against the revolutionary spirit of the times. In 1815 the monarche of the great continental states sought to strengthen themselves against revolution by forming what was termed the Holy Alli-ance, which, in reality, was merely a combination among the several members to aid each other in suppressing any attempts that might be made in favour of constitutional principles within the dominious of any member of the league. The last event that called forth much diplomatic skill was the late war with Russia, which was both ushered in and succeeded by a large amount of diplomacy. According to the Baron de Martens, whose work is still the chief authority on this subject, diplomacy is at the same time one of the most important and one of the most difficult by anches of human knowledge. The fate of a nation depends very much, in the present state of the world, upon its relations with others; and these, again, are materially influenced and determined by its diplomacy. The diverse and ever-changing relations subsisting between different states, dependent upon their character and constitution, their power, real or presumed, their alliances, discords, the vicissitudes of events, &c., all come under consideration in diplomacy. From history, from treaties, and from diplomatic correspondence much, indeed, may be learned; but these are not all. The same events may, indeed, reproduce themselves at different epochs, and the same subjects may come up for discussion; but a diversity of incidents, sudden and unforeseen events, the difference of manners, of interests and views, and the character of the actors, may so completely and suddenly change the aspect of affairs, that the same subjects may present, when least expected, a striking dissemblance, and the example which had been chosen may cease to furnish a line of conduct. The determining motives can only be seen from a full and entire knowledge of all the circumstances of the case; and the diplomatist must also have a forethought to the events more or less probable by which these may be modified or changed. The branches of knowledge which the diplomatist ought to be specially versed in, as given by Do Martens, are as follows:—1. The natural law of nations, and public law in general, which supply the fundamental maxims of all positive legislation in political matters. 2. The positive law of European nations, which is founded on treaties and usages which modify fundamental maxims, and regulate the relations modify fundamental maxims, and regulate the relations of the different nations, both in war and peace. 3. The public law of the principal states of Europe, which is founded on the laws of each particular state. 4. History and its subsidiary branches, particularly the history of wars, of negotiations, and treaties, which serve to make known the progress and tendency of cabinets. 5. The various political means that may be brought into contributes. brought into operation; as concession, retention, confederation, and the like. 6. Political economy, which shows how social wealth, independence, and organization form, distribute, and perfect themselves. 7. The geography and statistics of the separate states. S. The conduct of negotiations, or the course to be followed in treating of the interests of different states; and 9. The art of composing diplomatic dispatches. Diplomatic agents in Europe rank, according to the congress of Vienna, as follows:—1. ambassadors; 2. envoys extraordinary and ministers plenipotentiary; 3. ministers resident; 4. charges d'affaires; 5. secre-taries of legations and attachés; the last, however, diplomacy of his times. Artifices unknown to primitive diplomacy were freely resorted to, such as secret and diplomacy were freely resorted to, such as secret and one precise diplomatic character, and are only by separate articles in treaties; and it has been suspected that even sham treaties were promulgated, to mislead to the general public. During the period from the diplomacy of Europe Trench revolution (1789), the diplomacy of Europe assumed an aspect very different from that of the preceding century. The nations were exhausted by continued wars, and sought rather to cultivate the arts of peace, and industry and commerce were the arts of peace, and industry and commerce were the arts of peace, and industry and commerce were the arts of peace, and industry and commerce were the arts of peace, and industry and commerce were the arts of peace, and industry and commerce were the continued wars, and sought rather to cultivate the arts of peace, and industry and commerce were the arts of peace, and industry and commerce were the arts of peace are the arts of the secretary of the secretary of state for foreign affairs for this country the official organ and adtachés: the last, however, have no precise diplomatic character, and arts only by courtesy considered as attached to the legations. The courtesy considered as attached to the courtesy considered as attached to the courtesy

#### Diplomatics

hassadors abroad.-Ref. Baron C. de Martens, Le

Guide Diplomatique, 1857.

1) IPLOMATICS, dip-lo-mät'-iks, which is not to be confounded with the above, is the science of diplomas,—o founded with the above, is the science of diplomas,—of deciphering ancient writings, and judging of their churacter, value, date, &c. The most ancient diplomas that we possess do not extend beyond the 5th century of our ers, when parchment seems first to have come into general use, the material commonly used prior to that time being the leaves of the Egyptian papyrus. It is only since the middle of the 17th century that diplomatics has been raised to the dignity of a science, and its importance recognized as one of the chief sources of historical knowledge. The first who attempted to reduce it to a system was the Jesuit Papebroek, of Antwerp, who, about 1675, published a who attempted to reduce it to a system was the Jesuit Papebroek, of Antwerp, who, about 1675, published a work on this subject, entitled "Propylacum." He was succeeded by John Mabillon, whose able and learned work, "Do ke Diplomatica," first appeared at Paris in 1881. After him came Maffei, the Italian, whose work, "Istoria Diplomatica," was published at Mantun in 1727. The most learned and claborate work on this subject. work, "Istoria Diplomatica," was published at Mantua in 1727. The most learned and claborate work on this subject, however, and which has been of immense service to subsequent labourers in this field, is the "Nouveau Traité de Diplomatique," by MM. Tousaint and Tassin, two Benedictine monks of St. Maur, 6vols. 4to, Paris, 1750-65, with 100 plates. Diplomatics was reduced to a systematic form by Gatterer, in his "Elementa Artis Diplomatice" (1765), and afterwards in his "Abriss der Diplomatik" (1798). A more able work, however, was Schoenemanu's "Versuch eines vollständigen Systems der Diplomatik," 2 vols. (Hamb. 1804-1). Among the more recent works on this subject are Kopp's "Palcographia Critica," 4 vols. (Manh. 1817-29); and Pertz's "Schrifttafahr" (Hanover, 1846). In order to distinguish the authentic from the counterfeit, and to be able to say to what period a the counterfeit, and to be able to say to what period a diploma belongs, it is necessary to observe all its external marks and characters, the form in which it is made up, the parchment on which it is written, and the ink that has been used. It is not difficult for those who apply themselves to this study to distinguish the parchment as well as the ink of the ancients, from that of the moderns; but that which best distinguishes the original from the counterfeit is the writing or character itself, which is so different at different times, that one skilled in the science can generally tell with certainty, within forty or fifty years, when any diploma was written. All diplomas are written in Latin, and consequently the letters and characters have a general resemblance to each other; but there are certain strokes of the pen that distinguish not only the ages but the different nations among which they have been produced. The successive corruptions of the Latin tongue, the style and orthography of each age, as well as their dif-ferent titles and forms; the abbreviations, accentuations, and punctuation, and the different methods of writing the dipluthougs, all these form so many marks and characters by which the authenticity of a diploma is to be judged. Attention to these minute points is the more necessary, as some of the monks and priests were very expert at making counterfeits, and frequently enjoyed the confidence of princes and statesmen, being sometimes even intrusted with their rings and seals. The signature of the diploma consists either of the sign of the cross, or of a monogram or cipher, composed of the letters of the names of those who subcomposed of the name, and some scribed it. The initial letters of the name, and some times also the titles, were placed about this cross. By degrees, the custom changed, and they invented other marks. They sometimes added also the date and epoch marks. They sometimes added also the date and epoch of the signature, the feasts of the church, days of the calendar, &c. The seal annexed to a diploma was anciently of white wax, and artfully imprinted on the parchment itself. It was afterwards pendent from the paper, and inclosed in a box or case, which they called bulla. There are some also that are stamped on metal,

## Diptera

Dippel's animal oil, which contains an immense number of bases of great interest. It is often called bone-oil.

DIPPER (Cinclus), a gen. of birds of the Thrush sam, the British representative of which is the common dipper, or water-ousel. This bird is rather smaller than the thrush, of a dark-brown colour, with throat and upper parts pure white. The facility with which the dipper dives and pursues its prey beneath the water is very remarkable. It has been remarked that when it wades deeper than the knee, it displays its wings, and hangs them down. It was related by an eye-witness to Buffon, that this bird, when at the bottom of the water, appeared enveloped with air, which gave it a brilliant surface, like some kinds of beetles, which, when immersed in water, are always inclosed in a bubble of air. Its object in drooping its wings on entering the water may be to conflue the air. fam., the British representative of which is the comwings on entering the water may be to conflue the air. The dipper builds a very curious nest, composed of moss, domed, and with an entrance at the side: the site chosen is generally the bank of a stream, or sometimes under a cascade.

DIPPING-NEEDLE, dip'-ping.—This instrument consists of a frame in which a graduated circle is fixed in a vertical position. The frame itself moves on a graduated circle in a horizontal position, fixed on a small tripod that can be adjusted by means of levelling-screws. The needle is suspended on two knife-edges of agate, fixed in the frame exactly in the centre of the vertical circle, and moves freely in any direction in a vertical plane. When the vertical plane in which the needle moves coincides with that of the magnetic meridian of any place, the needle inclines from a horizontal position, and forms an angle with the horizontal line. This angle of inclination is called the dip of the nuc. This angle of inclination is called the dip of the needle. The dip varies like the angle of declination at different parts of the earth's surface, and at the same place at different periods. It also varies at different heights above the earth's surface. In 1576, when this property of the needle was first discovered by Robert Norman, the devression of the needle was property of the needle was first discovered by Robert Korman, the depression of the north end was about 71°,60°; in 1723 it had increased to 74° 42°; but at present it is about 68° 30°. When the plane of the needle is at right angles to the vertical plane of the magnetic meridian, the needle assumes a vertical position; but when it is in the plane of that meridian, the dip is the least. When the needle is in a vertical position, it gives us the means of determining the magnetic meridian by moving the vernier attached to the horizontal circle of the instrument over the space of 90°, which brings the vertical circle and needle into the plane of the magnetic meridian, and causes the latter to serve the purpose of a declination needle.

the purpose of a declination-needle.

DIFSACACE, dip. & levi-see e (probably from Gr. dipsac, I thirst), in Bot., the Teazel fam., a nat. ord. of dicotyledonous plants in the sub-class Coroliflore, consisting of herbs and undershrubs with opposite or verticillate leaves, and capitate or verticillate flowers surrounded by a many-leaved involuere. They are chiefly natives of the south of Europe, the Levant, and the Cape of Good Hope. Some are reputed to nossess astringent and febrifural properties. reputed to possess astringent and febrifugal properties, reputed to possess astringent and febritugal properties, but as remedial agents they are altogether unimportant. One very useful plant belongs to the order, namely Dipsacus Fullonum, the fuller's teazel, the dried heads of which have long been employed for dressing cloth. Their hooked bracts are just stiff enough to raise the nap, but too yielding to tear the

DIPSOMANIA, Or OINOMANIA, dip-so-mai'-ne-il (Gr. dipsa, thirst; oinos, wine; manta, madness), a term re-cently applied to an inordinate or insane craving for alcoholic stimulants. Lately medical men have come to the opinion that the inveterate drunkard is to be regarded as habitually under the influence of an insane impulse as naorcaary under the numerice of as insane impulse which it is impossible for him to resist, and which, therefore, renders him a fit subject for confinement or restraint. In 1844 the English lunacy commissioners urged the justice as well as the expediency of the confinement of habitual drunkards in our lunatic asylums,

bulla. There are some also that are stamped on metal, and even on pure gold.

Diplotegia, dip-lo-te'-je-a (Gr. diplos, double), in Bot., a kind of fruit resembling the ordinary capsule in every respect, except that it is inferior. It is the only inferior fruit which presents a dry dehiscent ericarp. Examples are seen in the campanulas.

Dipper's Oir, dip-pels, in Chem.—The dry distillation of bones yields a substance known to chemists as the distinguished to only both of the distinguished by having two clubbed appendages, called katteres or the distinguished by having two clubbed appendages, called katteres or the distinguished by having two clubbed appendages, called katteres or the distinguished by having two clubbed appendages, called katteres or the distinguished by having two clubbed appendages, called katteres or the distinguished the distinguished by having two clubbed appendages, called katteres or the distinguished the distin

#### Dipteracem

balancers, which seem to be the rudiments of two posterior wings. In ordinary language the dipters are called flies, usually with some characteristic prefix; such as the housefly, blow-fly, &c. The term fly, however, is often applied to insects which do not belong to the dipters; as butterfly, dragon-fly, May-fly, &c.
Mosquitoes, gnats, and midges belong to the diptera.
It is one of the most extensive of the orders of insects, and some of the species are remarkable for the extra-ordinary numbers in which they appear. The larvar of the order have frequently a membranous head, and always have the stigmats, or breathing-pores, confined to the second and terminal segments of the body. Dipterous insects are also distinguished by having the mouth in the form of a sucker, composed of from two to six lancet-shaped clongated scales, inclosing a canal upon the upper surface of the tongue or proboscis.

DIFFERCEE, dip-ter-ai'-se-e, in Bot., the Sumatra camphor fam., a nat. ord. of dicotyledons, in the subclass Thalamiflore, consisting of large trees, with simple alternate involute leaves and large deciduous convolute stipules. The flowers are perfect and symmetrical, being composed as follows:—Calyx and corolla each with five divisions; the former unequal, permanent, imbricated in sestivation, and ultimately enlarged so as to form wing-like expansions crowning the fruit; the latter with equal petals, and twisted in restivation. Stamens hypogynous, numerous, with beaked anthers. The fruit is 1-celled and 1-seeded; seed without albumen; radicle superior. The plants of this order are all natives of the forests of the tropical East Indies, with the exception of the genus Lophira, which belongs to tropical Africs. This genus has been placed in an order by itself, called Lophiracea, by some botanists. The useful products of the order are electresinous apparatuses. The DETERGRAPHS DESCRIPTION PRODUCTIONS OF THE PROPERTY OF THE mbstances. (See DIPTEROCARPUS, DRYOBALANOPS, Vateria.)

DIPPEROCAPPUS, dip-ter-o-kar'-pus (Gr., double-winged carpel), in Bot., a gen. of plants belonging to the nat. ord. Dipteraceae. Several species, as D. turbi-matus, costatus, alatus, and incanus, yield an oleo-resinous substance, called wood-oil or Gurjun balsam,

resmous substance, called wood-oil or Gurjun balsam, which resembles in its properties the so-called balsam of copaiba, and which is used for similar purposes. In India wood-oil has been employed for painting houses. Diptract, dip'der-iks, in Bot., a gen. of plants belonging to the nat. ord. Leguminosa, sub-ord. Papilio-macea. The seeds of D. odorata, a native of Guiana, have a very powerful and agreeable odour, which is due to the presence of a volatile oil containing coursering. They are need for securing a welf and in permarin. They are used for scenting snuff and in per-fumery, and are commonly called Tonquin or Tonks beans.

DIFFORE, dip'-tote (Gr. dis, twice; pipto, I fall), in Gram., is applied to a noun that has only two cases. DIFFICE, dip'-tik (Gr. diptuckon, folded together), properly signifies something folded, and was originally used in the same sense as diploma. Diptychs, however, were usually tablets of metal, ivory, or wood, of equal size, fastened together by a hinge or ring, and were frequently beautifully carved on the outside. They were early in use among the Greaks and Bonnara and were early in use among the Greeks and Romans, sud were also common in the early Christian Church, where they were used as registers. The ecclesiastical diptychs were of three kinds;—the diptycha mortuorum, in which the names of all such as had died in the odour of sanctity were enrolled; diptycha vivorum, containing the names of such as were still alive and deserved well of the church; and the diptycha episcope-rum, containing the names of distinguished bishops. Portions of these were read during the celebration of the mass; and it was also the custom in some churches for the descon to rehearse from these books the names of eminent bishops, saints, or martyrs, before they made oblation for the dead. The names of those excommunicated were erased from the diptychs; but they were again restored upon their readmission into the church.

DIRECT and RETROGRADE, di'-rekt ret'-ro-graid (Lat. directus, retro, backwards, and gradus, a step), in Astron., when the motion of any beavenly body is from tron., when the motion of any heavenly hody is from
west to east, or in the direction and order of the signs
of the zodiac, it is said to be direct; when the motion
is in the contrary direction, or from east to west, it is
It was designed to supply the place of the Liturgy, or
asid to be retrograde. The motion of all the heavenly

## Directory

bodies, except some of the comets, is direct. The apparent motion of the heavens is retrograde, because the earth a motion is direct. By the astronomers of the 15th and 16th centuries, bodies in direct motion were said to move in antecedentia, and those in retrograde motion, in consequentia.

Dieker, in Mus., a certain character placed at the

end of a staff to indicate to the performer the situation of the first note on the succeeding staff, and is for this purpose always situated on that line or space in its own staff which corresponds with the line or space occupied by the note which it is intended to announce in the

DIRECTOR, di-rek'-tor (Lat. dirige, I make straight), in general, is one who has the chief management of a scheme, design, or undertaking. More particularly, he is one of a number of persons chosen by a plurality of votes from among the body of proprietors to conduct the affairs of some joint-stock undertaking, as a bank, railway, assurance company, or the like. In most cases, the directors are required to be possessed of a certain amount of stock, and frequently also they are allowed a small honorarium for their services. whole of the directors, collectively, form the board of directors; and they are generally invested with certain powers by the acts of the legislature to which they owe their existence. In the case of banks there are usually two kinds of directors,—ordinary and extraordinary; the former for seeing to the ordinary business of the concern; the latter attending only on particular occasions. The office of a director is one of no small risk sions. The office of a director is one of no small risk and responsibility, and several stringent enactments have recently been passed regarding it. Act 20 & 21 Vict. c. 54, declares any person being a director, public officer, or manager of a company, who shall make, circulate, or publish, or concur in making, circulate. culating, or publishing, any written statement or account which he shall know to be false in any maaccount which he shall know to be take in any mar-terial particular, with intent to deceive any member, shareholder, or creditor, of such body or company; or with intent to induce any person to become a share-holder or partner therein, or to intrust or advance any money or property to such body or company, or to enter into any security for the benefit thereof, shall be guilty of a misdemeanor, and liable to penal servitude for three years. Directors generally have the super-intendence and management of all the uffairs of the company, except in such matters as require the approval of the general body of the proprietors. A portion of the directors usually retire annually by rotation, and their successors are nominated at a general meeting of the proprietors. Directors elect their own chairman, and may also delegate their powers to committees. The presence of a certain number of the directors, called a guorum, is necessary before any business can be transacted. They are required to keep minutes of all their meetings, and of all the business transacted at these meetings and of all the business transacted at these meetings, such minutes being transacted at these meetings, such minutes being signed by the chairman, and received as evidence of what took place. By Act 19 & 20 Vict. c. 47, regarding joint-stock companies, it is declared that if the directors shall declare a dividend when the company is known by them to be insolvent, or a dividend, the payment of which would render it insolvent, they shall be jointly and severally liable for the debts of the company when the payer is the payer of the company. that may be then existing, or that shall be thereafter contracted, so long as they may remain in office, provided the amount for which they shall be so liable shall not exceed the amount of the dividend declared.

not exceed the amount of the dividend declared.

Directors, di-rek'-tor-e, in the first French revolution, is the name given to the highest governing body to whom the executive authority was committed by the constitution of the year III. (1795). It was composed of five members, the first of whom were Barras, Rewbel, Lepeaux, Letourneur, and Carnot. They ruled in connection with the two legislative chambers, called the Council of Anoients and Council of Five Hundred. By the revolution of the 19th Brumsire (1769), this body and the constitution of the year III. were abolished. But the constitution of the year III. were abolished, and the consulate established

## Direct Taxation

It consisted of some general ment had abolished. heads, which were to be managed and filled up at discretion, for it prescribed no form of prayer or circum-stances of external worship, nor obliged the people to any responses excepting Amen. It forbids all salutaany responses excepting Altern. To other a same tion and civil ceremony in the churches. The reading of Scripture in the congregation is declared to be part of the pastoral office. All the canonical books of the Old and New Testaments (but none of the Apocrypha) are to be publicly read in the vulgar tongue. If pre-scribes heads for the prayer before sermon; and it delivers rules for the management of the sermon. The introduction to the text must be short and clear, drawn from the words or context, or some parallel place of Scripture. In dividing the text, the minister is to regard the order of the matter more than that of the words; he is not to burden the memory of his audience with too many divisions, nor perplex their understandings with logical phrases and terms of art; he is not to start unnecessary objections, and he is to be very sparing in citations from ecclesiastical or other human writers, ancient or modern. It recommends the use of the Lord's Prayer as the most perfect model of devotion. It forbids private or lay persons to administer baptism, and enjoins it to be performed in the face of the congregation. It orders the communion-table at the Lord's Supper to be so placed that the communicants may sit about it, and the dead are to be buried without any prevalent and the dead are to be buried. cants may sit about it, and the dead are to be buried such as it appears to us; for though they are really without any prayers or religious ceremony. It also sherical bodies, they are appearently circular planes, orders that the sabbath be kept strictly, both publicly that the sabbath be kept strictly, both publicly the diameter of the disc is considered as divided into and privately; that days of fasting or thanksgiving are twelve equal parts, called digits; by which means the two be observed, as may be deemed necessary; but that all festivals are to be abolished, and no day kept but In a total eclipse of either of those luminaries, the the Lord's-day. It also asserts that the singing of whole disc is observed or darkened; in a partial palms together in the congregation is the duty of Christians, and that no place is capable of any holimess in consequence of consecration. The use of the Directory was enforced by an ordinance of the Lords and Commons at Westminster, which was repeated in and Commons at Westminster, which was repeated in 1645, and a fine imposed upon such ministers as should read any other form than that imposed by the Directory. The king, in return, by a proclamation dated from Oxford in the same year, forbade the use of the

position performed at funerals.

DIRK, durk (Scot. durk), the name of a short dagger or poniard, now applied to the little weapon worn by

DIRK.

cadets in the royal navy. It appears to be derived from an old English verb, dirke, to stab, which is now It appears to be derived obsolete.

DIRT-BEDS, durt, in Geol., dark-coloured loam-like beds that occur interstratified with the colitic limestones and sandstones of Portland, and which are evidently the soils in which the eyeads and zamias of the period grew. Stumps of trees in an erect position, with their roots extending beneath them, have been found in these strata.

Drs, dis (Lat.), a prefix or inseparable preposition derived from the Latin, whence the French day. signifies a separation or parting from, and has thus the

signifies a separation or parting from, and any subset force of a privative or negative in meaning; as in the words dis-able, dis-oblige, &c. In some cases it still signifies separation; as in dis-connect.

DISABILITY, dis-ābil'-e-te (Lat. dis, and habilis, able), is the incapacity of a person to do any legal act. It is said to be absolute when it wholly disables a person,—

# Disciple

ness, and the like. Disability is ordinarily said to arise in four ways,—(1) By the act of the ancestor; (2) by the act of the party himself; (3) by the act of law; and (4) by the act of God.

DISAFFOREST, or DEAFFOREST, dis'-af-for-est, in Law, is to discharge from being a forest; to reduce from the privileges of a forest to the state of common

ground.

DISBAR, dis-bar', in Law, is to expel from the bar; to degrade a barrister from his rank or position. In England this power is vested in the benchers of the four inns of court; but it is never exercised except in very flagrant cas

Disc, disk (Lat. discus), in Bot., a term now applied to whatever intervenes between the stamens and the ovary upon the thalamus. It presents great variety of forms: thus in the Orange it forms a fieshy ring, surrounding the base of the pistil; in the Tree Paony, the dark-rad ann-shaped averaging covaring nearly the a dark-red cup-shaped expansion, covering nearly the whole of the pistil except the stigmas; in the Rose, a sort of waxy lining to the tube of the calyx; in umsort of waxy lining to the tube of the calyx; in umbelliferous plants, a swelling on the top of the ovaries, adhering to the styles. In other cases, the diac is reduced to little separate glandular bodies, as in cruciferous plants; or to scales, as in the Vine; or to various petaloid expansions, as in the Aquilegia.

Disc, or Disk, the body or face of the sun or moon, such as it appears to us; for though they are really spherical bodies, they are apparently circular planes. The diameter of the disc is considered as divided into twelve could parts, called digits: by which means the

substance; a thin circular plate of any substance.

DISCHARGE, dis-tsharj' (Fr. dicharger), in Mil., the term applied to the release of a non-commissioned officer or private from the duties which he has voluntarily undertaken for a certain number of years at the time of his enlistment. When the end of the time for which he from Oxford in the same year, forbade the use of the has agreed to serve has arrived, he can legally claim Directory, and enjoined the continuance of the Liturgy. his discharge; but should he desire to leave the regiment and the General Assembly of ment before his period of service has ended, he must the Church of Scotland adopted the Directory. Many obtain the permission of his commanding officer to do of its regulations are still complied with in that clurch, so, and pay a certain sum in compensation for the loss and it is usually appended to the Confession of Fuith. of his services. This sum is generally about £20; but, if he be a skilled artisan in the engineers or artillery, he may have to pay as much as £35 or £40. When as he may have to pay as much as £35 or £40. Soldier is discharged for misconduct, he is degraded bridged to the control of the antiphona "Dirige Domine Deus," chauted stripes, buttons, and facings torn from his uniform, in the funeral service of the Roman Catholic church.

It is now used to express a solemn and mournful companions of the service. At the solemn control of the service. At the solemn control of the service. The time of his discharge, every soldier receives a certificate the service of the service. stripes, buttons, and facings torn from his uniform, and he is then "drummed out" of the service. At the time of his discharge, every soldier receives a certificate, signed by the commanding officer of the regiment, stating his character and the time for which he has served.

DISCHARGING-ROD, dis-tsharj'-ing, an instrument much used in electricity for discharging Leyden jars

without partaking of the shock. The jointed discharging rod is that most generally employed. It consists of two brass wires, terminated by two brass balls. The wires are jointed at the middle, and are attached to a glass handle. With this instrument glass handle. With this instrument it is easy to discharge a jar or battery, by bringing one ball in contact with the exterior, and the other with some part of the interior. The glass handle, as an insulator, forms a pro-tection from all the effects which take place in the restoration of elec-trical equilibrium.

ROD.

DISCIPLE, dis-i'-pl (Lat. discipulus, from disco, I learn), strictly means one who learns anything from another; and hence the followers of any teacher, philosopher, or head of a sect, came to be called his disci-ples. In this sense it is sometimes used in Scripture; DISABILITY, dis-d-bil'-e-te (Lat. dis, and habilis, able), is the incapacity of a person to do any legal act. It is said to be absolute when it wholly disables a person,—sa outlawry, excommunication, attainder, alienage; or as outlawry, excommunication, disables, disables are so that the last of these,—the followers of Jesus. Sometimes all who received the doctrines of Christ are partial,—as infancy coverture, idiotey, hunacy, drunken—659 ples.

## Disciplina Arcani

plied to the seventy or seventy-two persons that were his more immediate followers and attendants. Sometimes it is used as synonymous with apostles, and

times it is used as synonymous with aposties, and applied to the twelve.

DISCIPLINA ARCANI, dis-e-pli'-nd ar-kai'-ni (Lat., discipline of the secret), in Ecol. Hist., is the name given to a system that prevailed in the early primitive church, of concealing from unbelievers, and even from catechumens, certain parts of their worship, and especially the sacraments. Even ministers, when led in their public discourses to speak of the sacraments or the higher doctrines of faith, contented themselves with remote akusions, adding, "the initiated know what is meant." It is difficult to account for the introduction of a system so contrary to the spirit of Christianity. Neander supposes that it took its rise in the church of Alexandria, whence it extended first to the Eastern and afterwards to the Western churches. It appears to have been gradually established after the 2nd century, and is supposed to have reached its perfection during the 4th.

Discripting, dis'-ip-lin (Lat. disciplina), signifies literally instruction, cultivation, improvement; but it is applied figuratively to a rule or order of government; a particular mode of life, in accordance with the rules of some profession or society; also chastisement or correction, bodily punishment or morbification. In military matters it denotes obedience to and exercise of the laws and regulations of the service. In ecclesiastical affairs it is the putting in force of the laws instituted by any particular church to preserve its unity, purity, and usefulness. At an early period of the Church, it consisted in depriving the offender of all the privileges and benefits of baptism, by turning him out of the society and communion of the Church. The offender was first solemnly admonished once or twice, before he was cut off from the communion, or expelled from the Church. The person was then held to be excommunicate, and the faithful shunned and avoided him.

Discripint, Books or, in the Eccl. Hist. of Scotland, are certain documents drawn up and published for the direction and guidance of the reformed church in that country. The first Book of Discipline was drawn up, at the request of the General Assembly of 1560, by John Knox and other eminent Scottish reformers of the time, approved by the General Assembly, and subscribed by the majority of the nobles and inferior barons and gentry composing the privy council of the kingdom. It was characterized by a vigorous exercise of ecclesiastical discipline against all offenders; for, say they, "the kirk of God can neither be brought to purity, nor yet be retained in the same, without the order of ecclesiastical discipline, which stands in reproving and correcting the faults which the civil sword doth not or may not punish." In this matter they followed the example of the early Christian church; for they justly regarded the relaxation of discipline under the papacy as one great cause of its universal corruption. It is also worthy of remark, as showing the advanced views of the authors of this document, that it takes special notice of the subject of education, viewing it as necessarily connected with religion. It lays it down as imperatively necessary that there should be a school in every parish, for the instruction for youth in the principles of religion, grammar, and the Latin tongue; and it further proposed that a college should be receted in every "notable town," in which logic and rhetoric should be taught, along with the learned languages; for "the rich and potent may not be permitted to suffer their children to spend their youth in vain idleness, as heretofore they have done; but they must be exhorted, and, by the censure of the church, compelled to dedicate their sons, by Itraining them up in I good exercise, to the profit of the kirk and commonwealth; and that they must do of their own expenses, because they are able. The children of the poor must be supported and sustained on the charge of the kirk." The Second Bo

#### Discontinuance

State; and it begins by laying down the essential line of distinction between the two powers. The civil power appertains to the civil government of the common-wealth; the ecclesiastical power flows immediately from God and the Mediator Jesus Christ, and is spiritual, not having a temporal head upon earth. Civil authority has for its object the promoting of external peace and quietness among the subjects; ecclesiastical authority, the direction of men in matters of religion and which pertain to conscience. The former enforces obedience by external means, the latter by spiritual means; and as they be both of God, and tend to one ead, they ought to co-operate within their respective spheres, and fortify one another. There are three kinds of church officers,—ministers, who preach and rule; cletre, who are merely rulers; and deacons, who act as distributors of alms and managers of the funds of the church. The office-bearers are to be admitted by election and ordination, and none are to be intruded contrary to the will of the congregation to which they are to be appointed. The document, says Dr. McCrie, "is a form of ecclesiastical polity, whose practical utility has been proportioned to the purity in which its principles have been maintained. Accordingly, it has secured the cordial and lasting attachment of the people of Scotland. . . And the principal secessions which have been made from the national church in this part of the kingdom have been stated not in the way of dissent from its censtitution, as in England, but in opposition to departures, real or alleged, from its original and genuine principles." (Life of Metville.)—Ref. Hetherington's History of the Church of Scotland.

Discipline, Military and Naval, a general term applied to the rules for regulating the behaviour of soldiers and sailors. Discipline is maintained and directed by the War-office and the Admiralty; and the Articles of War and the Mutiny Act are the principal grounds upon which they act. In practice, the adjutant maintains regimental discipline; and the adjutant general is in relation to the whole army what the adjutant is to his regiment. The regimental adjutant superintends the drill and field movements, inspects the guards, escorts, &c., receives garrison orders, keeps regimental books, &c. The military discipline of volunteer regiments is maintained by adjutants appointed by the War-office.

DISCLAIMER, dis-klaim'-er (Lat. negative dis; clamo, I call for), in Law, is a plen in which a party in a suit disclaims or denies all interest in the matter in question. It is more particularly applied to the denial by an alleged tenant of nis tenancy, which operates as a forfeiture of the lands to the lord, if he succeed in received in terms of the lands to the lord, if he succeed in

proving his terancy.

DISCONTENT, dis'-kon-tent (Lat. dis, and contentus, content), is dissatisfaction with our present condition, and is not only a source of wretchedness to the individual himself, but of annoyance to all with whom he may be brought into contact. It is generally owing, not so much to the actual circumstances of the individual as to a bad condition of mind, leading him to contrast his condition with that of those whom he regards as placed in more favoured circumstances than himself, without considering the many points in which he is more favoured than others. Discontent frequently springs not so much from actual ills, as from a dread of those which are expected. But, as pleasures are rarely so great in actual enjoyment as in anticipation, it is the same with evils. All experience testifies to the truth of the Christian maxim, that "sufficient for the day is the evil thereof," while every one's past history must furnish him with instances of what at the time he regarded as evils, but which eventually turned out for good.

DISCONTINUANCE, dis'-kon-tim'-u-dias (Lat. dis, and

training them up in j good exercise, to the pront of the kirk and commonwealth; and that they must do the kirk and commonwealth; and that they must do of their own expenses, because they are able. The children of the poor must be supported and sustained on the charge of the kirk." The Second Book of Discipline was adopted by the General Assembly in 1578, and, though never formally ratified by act of parliament, it is still regarded as the standard work on matters of order and administration by Scotch Presbyterians. It was prepared at a time when much continued to the course of a thing; as a discontinuance of possession, of a plea, of a process, &c. Discontinuance of possession, of a plea, of a process, &c. #### Discords

maintain it. It is not necessary for that purpose to obtain the defendant's consent, but the plaintiff must

obtain the defendant's consent, but the plaintin must undertake to pay the costs.

Discords, dis'-kords (fr. discords), in Mus., a dissonant or inharmonious combination of sounds, so called in contradistinction to concord, the effects of which it is intended to sweeten and relieve. Some require to be introduced by certain preparatives, and to be succeeded or resolved by concords to which they have some reletion. Therefore, are sometimes intended to the contradiction of the contradiction have some relation. Discords are sometimes intentionally introduced into music, not for themselves alone, but to set off the concords by contrast and opposition. Their necessity in the composition of part music can-not be denied, as they not only improve the concords not be defined, is they not only improve the concords by opposition, but by causing a momentary distress to the ear, which remains unsatisfied and even uneasy until it hears something better, they give a stimulus to the attention, which would otherwise languish.

Discordant, dis-kord-ant.—All dissonant or inhar-

monious sounds, whether successive or simultaneous,

are thus called.

DISCOUNT, dis'-kownt (Sp. descontar), is an allowance made on a bill, or any other debt not yet become due, in consideration of present payment. It is usual in commercial dealings to allow for discount a sum equal to the interest on the debt from the time of payment to the time when it actually becomes due, which sum is deducted from the whole amount. This mode of calculation, though generally adopted, is not strictly correct; for it is evident that in this way the discounter receives more than he is actually entitled to. Thus, if a bill for £100 due twelve months hence be discounted at the rate of 5 per cent., the holder only receives a present payment of £:5, which, by being lent out at 5 per cent., will in twelve months only produce £4.15s.24d., which is the true discount on the bill. The person who, at the end of twelve months, receives £100 for an advance of £95, actually receives of interest £5.54.3d, per cent. The rate of discount varies according to the demand for money and the character or credit of the parties sub-scribing to the bill. The rate of discount upon good bills is usually from 3 to 4 per cent. When merchan-dise is purchased at a fixed term of credit, the discount allowed for payment before the expiry of that term is usually considerably above the current rate of interest, as the creditor is thus insured against the insolvency of the debtor. The depreciation in value of any fixed in-vestment is also called discount. Thus, if the market value of a railway share on which £100 had been paid is only £90, it is said to be at a discount of 10 per cent.

Discourse, dis-korse (Lat. discursus, from dis, and curro, I run), in Log., is an operation of the mind, whereby it passes or proceeds from one thing to another,—from a thing known to one unknown, and is thus synonymous with reasoning (which see). In Rhet, it is used in the same sense as an oration, a series of sentences and arguments arranged in a regular manner, with a view to carry conviction to the minds of those to whom it is addressed. It is also sometimes applied to the familiar talk or conversation

of an individual.

Discoveny, dis-kur'-e-re (Fr. découvrir, to discover), in Law, is the act of disclosing or revealing any matter. Till recently, the courts of common law had no power to compel a litigant before them to disclose any fact resting morely within his knowledge, or to discover any document in his power or possession. This defect has been remedied by recent enactments; and it is now competent for litigants, and they may be com-pelled to give evidence on the trial of such action, the credibility of which evidence to be decided by a jury. The judges may also, on application by either of the litigants, compel the opposite party to allow the applicant to inspect all documents in his custody or under his control relative to such action or proceeding.

DISCRETION, dis-kresh'-un (Lat. discretio, a separating), is that kind of prudence or discernment which enables a person to judge critically of what is correct enables a person to judge critically of what is correct and proper in certain circumstances, particularly as regards his own conduct. In Law, discretion is the power or faculty of discerning between right and wrong. "There are," say's Addison, "many more shining qualities in the mind of man, but there are mone so useful as discretion. It is this, indeed, which

#### Disease

gives a value to all the rest; which sets them at work in their proper times and places, and turns them to the advantage of the person who is possessed of them."
"Discretion is the perfection of reason, and a guidato us in all the duties of life." It "points out the noblest ends to us, and pursues the most proper and laudable methods of attaining them."

DISCUS, dis kus (Gr. diskos), a queit used by the ancients. It was generally a heavy circular piece of iron, sometimes perforated in the middle. The discus was not thrown at a mark, but the players endearoured who could throw it the farthest. The practice of throwing the discus is mentioned by Homer as being one of the sports at the funeral of Fatroclus. In the Cabinet of Antiquities at Paris, a discus is preserved which contains holes for the insertion of the thumb and fingers. In the well-known statue of Discobolus throwing the discus, in the British Museum, one of

the methods of using it may be seen.

Discussion, dis-kus'-shun (Lat. discutio), in Scots Law, denoted the doing diligence by a debtor against the principal creditor before coming against his cautioners or sureties, which was necessary to be done, unless the latter bound themselves as principals, or renounced the benefit of discussion. By the Mercanrenounced the benefit of discussion. By the Mercan-tile Law Amendment Act (19 & 20 Vict. c. 60), the right of discussion was abolished, and can now only be enjoyed by express stipulations, or in the case of cautioners bound prior to the passing of that act. Discussion, dis-kus'-shun (Lat. discussio, a shaking

off), in Lit., denotes the clear treating or handling of any particular point or problem, so as to shake off the difficulties with which it is embarrassed. Thus we say such a point was well discussed when it was properly treated and cleared up. (See CONVERSATION, DEBATE.)
DISCUTTENT, dis-ku'-te-ent (Lat. discutio, 1 destroy),

in Med., are remedies that discuss or disperse morbid

matter.

DISEASE diz-zeze' (Ang.-Sax.), is a departure from the state of health in which the due balance between the several parts or properties of the animal frame is maintained. It is "a changed condition or proportion, in function or structure, in one or more parts of the body." Diseases of function are deviations from a standard furnished by physiology, and diseases of structure a departure from a standard supplied by These, however, are usually combined; for there is seldom structural disease without some disor-der of function; and in many instances functional diseases are, or ultimately will be, accompanied by change of structure. The causes of disease may be either intrinsic, existing within the body, or independent of any obvious external influence; or they may be extrinsic, having their origin without the body. latter embrace all the external agencies that can operate either on body or mind; as temperature, air, food, poison, sensual impressions, and the like. Causes of disease, however, are often present without disease ensuing, some frames being less susceptible to particular causes of disease than others. Hence physicians distinguish two kinds of causes,—predisposing and exciting; the former being circumstances which so influence the functions or structures of the body as to render it unusually susceptible to the influence of particular exciting causes,-that is, of such circumparticular exciting causes,—that is, of such circumstances and agents as seem to more immediately operate in producing disease, especially when in a state of predisposition. The predisposing causes of disease are said to be,—(1) Debilitating influences; (2) excitement; (3) previous disease; (4) present disease; (5) hereditary constitution; (6) temperament; (7) age; (8) sex; (9) occupation. The exciting causes are so termed because the diseases seldom uplas their approximation products that have them present: make their appearance unless they have been present; and hence they have come to be regarded in the light of excitements to it. They are divided into cognizable and non-cognizable agents; the former comprehending those physical and mental influences of whose existence we can take cognizance independently of their operation in producing diseases the latter work their operation in producing disease; the latter such as clude our senses, and whose existence we only infer from their morbific effects. The cognizable agents are,—(1) Mechanical influences; (2) chemical influences; (3) ingesta; (4) bodily exertion; (5) mental emotion; (6) excessive evacuation; (7) suppressed or

#### Disfranchise

defective evacuation; (8) defective cleanliness, venti-lation, or drainage; (9) excesses and changes of tem-The noncognizable agents are endemic, epidemic, and infectious poisons, and are sometime spidemic, and infectious poisons, and are sometimes termed symotic (Gr. suma, a ferment). The classification and arrangement of diseases according to their external characters is termed Nosology; and that branch of science which more particularly regards the nature and progress of disease with a view to its cure, is called Pathology. (See NOSOLOGY, PATHOLOGY.)—Ref. Williams's Principles of Medicine.

DISPRANCEI In such a case it is necessary for the holder, or person in whose favour the bill is drawn, to give notice to the drawer and indorsers of the dishonour of the bill within a reasonable time, so as to preserve his recourse

against them.

DISINFECTANTS, dis-in-fek'-tänts (Lat. dis; Fr. in-fecter, to infect).—Disinfectants are substances which, by combining with deleterious gases or emanations, decompose them and render them harmless. powerful disinfectant known is chlorine, which is generally employed for this purpose in the form of chloride Another powerful disinfectant is permangaante of potash, which acts by yielding up an equivalent of nascent oxygen. It is known in commerce as "Condy a disinfecting fluid." Carbolic acid in solution is also a powerful means of getting rid of noxious rapours. To the constant use of these and other disinfectants by the different boards of health throughout the country may be attributed the great decrease of fever and other contagious disorders amongst the

DISINTEGRATION, dis-in-te-grai'-shun (Lat. dis, in-teger), the act of separating the integrant parts of a substance, as distinguished from decomposition, or the separation of constituent parts. Disintegration refers more particularly to the mechanical diffusion of a aubstance; decomposition, to the chemical division.

DISJUNCTIVE CONJUNCTION. (See CONJUNCTION.) DISJUNCTIVE PROPOSITION, dis-junk'-tiv (from Lat. sis, and jungo, I join), in Log., is a proposition com-pounded of two or more categorical propositions, so stated as to imply that one of them must be true. In such a case we proceed either by asserting the truth of one member of the division, and thence inferring the falsity of all the rest, which is called the modus ponens; or else by asserting the falsity of all the members but one, and hence inferring the truth of

that one, which is called the modus tollens.

DISLOCATION, dis-lo-kai'-shun (Lat. disloco, I put out of place), is the displacement out of their natural position of bones articulated together or forming a position of bones articulated together or forming a joint. It is usually occasioned by external violence; but may also, in some cases, result from diseases of the joint. Dislocation is either complete or incomplete; being incomplete when the articular surfaces remain partially in contact, and complete when there is an emire separation. It is simple when there is no wound and the skin remains unbroken; compound, when there is a mound by means of which the arterial is reis a wound, by means of which the external air may communicate with the joint. When, besides the dis-location, there are fractures of the bones or laceration of important organs, then it is termed a complicated dislocation. Dislocations are named either from the joint or from the bone that is chiefly displaced; and various terms are likewise employed to indicate the direction; as upward; downward, forward, backward, &c. Nearly all the bones of the human body are liable to displacement; but some are much more so than others; as those of the shoulder, hip, elbow, aukle, &c. Generally, those joints are the most liable to dislocation that admit of the greatest extent of motion. eation is in most cases easily observable; but in some eating it in mose cases easily conservate; but it some parts it is extremely difficult of detection. It is at-tended with loss of power and motion in the part, with more or less of swelling and pain, which is increused on moving the part; the putient feels sick and faint, and there is a sensation of numbness in the part. Disloca-Legre is a sensition of numoness in the part. Dislocations should be reduced as soon as possible after their Distribution, dispensation, dispensation, dispensation, dispensation, or the act of dealing difficult will be the operation. In a short time the out to different places or things. In Theol., it is

### Dispensation

patient recovers from the shock of the accident; the muscles, which were at first relaxed, resume their former rigidity, and render the reduction much more difficult. Dislocations are reduced by pulling gently, yet firmly and steadily, for some minutes, until the muscles are fatigued, and the head of the bone brought down below the level of the joint, when, by being gently lifted over the edge of the cocket, it falls into its place, upon the extending force being slightly re-laxed. The force required is often very considerable, and sometimes it is necessary to have recourse to a block and pulleys, in which case the body is securely fixed by proper bandages to a staple in the wall, or other sufficient support. In order to overcome the violent contraction of the muscles, it was sometimes necessary formerly to weaken the patient by blood-letting, emetics, &c.; but latterly chloroform has been most commonly resorted to for this purpose. After reduction it is necessary that the joint be kept in a state of perfect rest for some time, in order to allow the ruptured ligaments to unite; otherwise the accident will ever afterwards be liable to recur. When a dislocation has been left unreduced, the parts come to adapt themselves to their new situation; a new socket is formed for the head of the bone displaced, the old socket becoming absorbed or filled up. pound dislocations are generally attended with danger, and, when occurring in the large joints, are usually fatal, or require amputation. The displaced bones should be replaced without delay, and with as little violence or disturbance as possible, and the external wound closed. Sometimes, however, it is necessary to dilate the wound, in order to effect the reduction or to remove the detached pieces, if the end of the bone should have been shuttered. If there is surrounding inflammation, leeches should be applied to the part.

DISLOCATION, in Geol. (See FAULT.)
DISMES, dis'-mes (Lat. decima, or tenths), the name DISMES, dis-mes (Lat. decima, or tentins, the name given to the tenth part of the yearly value of all spiritual benefices anciently paid to the pope, who claimed this tithe of the tithes on the principle that the Jawish high priest took tithes of the Levites. This was frequently a cause of dissatisfaction to the English kings, and led to frequent disputes with the papal power. At the time of the Reformation these were annexed to the crown; and in the reign of Queen Anne the tenths and first-fruits were granted for the augmentation of poor livings, under the name of Queen Anne's Bounty. (See BOUNTY, QUEEN ANER'S.)
DISPATCHES, dis-patsh' ez (from Fr. dépêcher, to send

away), a term applied to a letter, or packet of letters, sent with expedition by a messenger express. It is mostly used when referring to a letter or letters on some affair of state or public concern. Papers containing information sent by some public officer to the government on public business are always called dis-

patches.

DISFRNSARY, dis-pen'-să-re (Lat. dispensarium, from dispendo, I distribute), denotes properly the shop or clace in which medicines are made up and distributed, but is now more commonly applied to a charitable institution for supplying medical advice and medicines gratuitously to the poor. These valuable institutions are only of recent origin, but they are now to be met with in every town of any importance either in this country or on the continent. Attached to each are country or on the continent. Attached to each are generally one or more physicians and surgeons, who, besides attending at the institution, visit at their own houses those that are too ill to attend personally. There is also a resident medical officer for dispensing the medicines. In most cases dispensaries are supported by voluntary contributions and a subscriber of a certain sum annually, or at once, becomes a governor, and is entitled to have one patient always on the books. "It would," says the English Cyclopædia, " be a great improvement in the principle of these institutions, if some contribution towards their support were required on the part of the poor themselves, which would enable the independent labourer, without asking charity, to procure the best advice for his sick family at a much cheaper rate than he can possibly do at present."

#### Dispensation

applied to the dealings of God with his creatures, particularly in some unusual or extraordinary way. In some cases it has reference to those providential ordinations by which the world was prepared for the gospels. Sometimes it has reference to the system of principles or rites enjoined by divine authority; as, the Mosaic dispensation, the Christian dispensation.

DISPENSATION, in ecclesiastical matters, is a relaxa-

tion of the law, or a dispensing with obedience to it in certain cases, granted by one who has the power to do so. The pope, as being above the law, claimed to have the power of dispensing with obedience to it in such the power of dispensing with obedience to it in such cases as he thought fit,—a power which was at one time frequently exercised, and led to great irregularities. By 25 Hen. VIII. c. 21, the power of granting dispensations as previously exercised by the pope was transferred to the archbishop of Cauterbury, but with the following important restrictions:—(1) That nothing be ropugnant to the law of God, for king or subject; (2) that nothing be against the statute 21 Hen. VIII. argainst pluralities of henefices. (3) nor against the against pluralities of benefices; (3) nor against the king's prerogative, or laws or statutes of the realm; and (4) that he 's limited to such as shall appear convenient and necessary, upon examination of the causes and qualities of the income. Hence it is that the architecture. bishop has authority to grant special licenses for the celebration of marriage, and for clergymen to hold

DISPENSATORY, dis-pen'-să-to-re, is a book containing the method of preparing the various kinds of medicine used in pharmacy. Almost every country in Europe, and many of the large cities, have their own dispensatories, which the apothecaries are bound to follow.

DISPERSION, dis-per-shin (Lat. dispergere, from dis, a particle denoting separation, and spargere, to scatter), the term applied to the separation of a ray of white light into its several component coloured parts by refraction, through the instrumentality of a prism. (See Prism.) When a ray of white light, or light from the sun, is allowed to enter a darkened room through a very small hole made for the purpose in the shutter by which the light is excluded from the apartment, and allowed to fall on a screen of white paper, conveniently fixed to receive it, it will cause a bright spot to appear on the screen, larger or smaller, in proportion to the distance of the screen from the window, and round or oval in shape, according as the ray falls on it at right angles to it, or at any angle which is not a right angle. If this ray be intercepted by placing one of the wedge-shaped edges, or angles formed by the meeting of any of the planes that compose the sides of the prism, in the bright track of light passing from the hole to the screen, it will be refracted or bent, and the white light will be dispersed, or, in other words, decomposed and separated into its various component parts of coloured light. We are made aware of this by the change in the position and appearance of the spectrum, as the bright spot of light that falls on the screen is called. Its new position is considerably above or below the original one, according to the way in which the ray of light enters the apartment, which shows that the ray, instead of proceeding to the screen in a straight line as before, has become bent out of that direction in its passage, and the spectrum, if previously round, has now become oval, or, if oval, considerably clongated in form, and, instead of looking like a spot of uniform bright appearance, the luminous space is covered with horizontal bands of colours arranged in the following order,—red, orange, yellow, green, blue, indigo, violet. These orange, yellow, green, blue, indigo, violet. These colours appear in the order of their refrangibility or capability of refraction, some being subject to a greater degree of refraction than others; that of blue being greater than that of yellow, and yellow greater than red. The breadths of the spaces occupied by the different colours are not in the same ratio to each other for every kind of prism; that is to say, the ratio of the spaces occupied by the colours differs according to the kind of glass of which the prism is made, and the length of the spectrum also differs. This is called the irrationality of dispersion. The best method of trying irrationality of dispersion. The best method of trying the experiment of dispersion of light is to allow the the experiment of dispersion of light is to allow the sun's rays to enter the apartment through a long and very narrow slit, instead of through a circular hole, which will give a spectrum of greater breadth. In Optics the term is often applied to the reflection or

#### Dissenters

scattering of rays of light from any polished and reflecting surface, such as a steel mirror or looking-

DISPERSION OF MANKIND, is that event which took place at the building of the tower of Babel, in coasequence of the confusion of tongues.

DISTONDER, dis-spon'-de (Lat. di and spondee) Greek and Latin poetry is a double spondee, or a foot consisting of four long syllables; as, juramentum.

DISPOSITION, dis-po-zieh'-nn (Lat. dispositio), in

Log., is that operation of the mind whereby we put the ideas, propositions, or arguments which we have formed concerning a subject, in the order fittest to gain a clear knowledge of it, to retain it in the memory, or to explain it to others. In Rhet, it is the due placing or ranging the several parts of a speech or discourse. The logician is tied down to a certain prescribed form in his mode of reasoning, the rhetoriciae adopts that mode that seems most convenient for bim.
"A discourse," says Quintilian, "that wants disposition must necessarily be confused and without connection, liable to frequent tautologies and omissions, and, like one wandering in the dark, be conducted by chance rather than design." (See Oratora). Disposition likewise denotes a particular state of mind, distinguishing one individual from another, and inherent in the constitution.

DISPOSITION, in Scots Law, is a deed of conveyance by which property, either heritable or movable, is conveyed or transferred from one party to another.

DISPUTATION, dis-pu-tai'-shun (Lat. dis, and puts, I

DISPUTATION, dis-pu-tait-shan (Lat. dis, and puts, it hink), is a discussion or contest, either by word or writing, on some unsettled question. (See DRBATE.)
DISQUISITION, dis-kwe-rish'-in (Lat. dis, and quere, I seek), is a formal or systematic inquiry into the nature, kinds, or circumstances of any problem, question, or topic, by arguments, or by discussion of the facts and circumstances, in order to elucidate the truth, or to obtain clear notions regarding it.
DISRUPTION, dis-rup'-tshan (Lat. dis. and runnes. I

Disturritor, dis-rup'-tshua (Lat. dir, and ramps, I break), in the Eccl. Hist. of Scotland is applied to that act by which upwards of four hundred ministers of the established church left their churches and manses, in 1843, in vindication of their principles, and formed themselves into what has since been known

as the Free Church. (See FREE CHURCH.)

DISSECTION, dis-sek'-shun (Lat. dis, and seco, I out), is applied to the cutting or dividing of the different

parts of the body in anatomy. (See ANATOMY.)

Dissessing a man of his laud or estate, or interrupting his seisin. (See Shisin.)

Dissenters, dissenters (Lat. dis, and sentio, I think), in Eccl. Hist., is the general name applied to all the religious sects in this country that different the established church, in doctrine, discipline, or mode of worship. The Roman Catholics and or mode of worship. The Roman Catholies and Jews, however, are not usually classed with dissenters. The origin of Protestant dissent from the Church of England is usually traced to the reign of Edward VI., when, by the Act of Uniformity, passed in that reign, dissent from the worship and ceremonies of the established church was rendered a penal offence. Dissenters became much more numerous in the reign of Elizabeth, and from their professing extraordinary purity in worship and conduct, they received the name of Puritans. During that and several of the succeeding reigns, a variety of laws were passed for the re-pression of dissent, of the most rigorous and oppressive character. During the rebellion the laws against Protestant dissenters were repealed; but they were revived at the Restoration, and the parliament of Charles II. proceeded to enforce, systematically, by new measures of rigour, the principle of universal connew measures of rigour, the principle of universal con-formity to the established church. By the Act of Uniformity (13 & 14 Car. II. o. 4), it was enacted that the Book of Common Prayer, as then recently revised, should be used in every parish church, and other place of public worship; and that every schoolmaster and person instructing youth should subscribe an acknow-mathematic declarate that he would conform to the

and the two Conventicle Adis, in 1864 and 1670, made it penal for five persons, in addition to the occupiers of a house, to assemble for religious worship. In 1665, the Five-mile Act imposed a penalty of £40 on every Nouconformist minister who came within five miles of any corporate town. In 1673, the Test Act excluded dissenters from all civil offices and military commands. The revolution of 1689 unhered in an era of more liberal measures for the dissenters. The Act of Toleration (1 Will. & Mary, c. 18) bestowed on Protestant dissenters full liberty of worship upon paying tithes and other dues, taking the oaths of allegiance and supremacy, and certifying their places of worship to the bishops or justices of the peace; dissenting ministers being also required to sign thirty-five and a half of the Articles of the established church. From that time, and the two Conventicle Acts, in 1664 and 1670, made it Articles of the established church. From that time, various statutes have been passed, extending a greater degree of freedom to dissenters; and in 1828 the Test and Corporation acts were ubolished. The oldest of the dissenting bodies are the Presbyterians, Independents, Baptists, and Quakers. About the middle of list century sprang up the Methodists, followers of Wesley and Whitfield, who soon became very numerous, but are now divided into a number of different sects. According to the census of 1851, which, however, is confessedly imperfect, there were, in all. 34,467 places of worship, having, in all, 10,212,563 sittings, in England and Walley; of which 20,390, with 4,894,648 sittings, belonged to the several bodies of dissenters, including Roman Catholics and Jews. Of these, 161 places of worship, with 85,812 sittings, be-Articles of the established church. From that time, these, 161 places of worship, with \$3,812 sittings, belonged to the Presbyterians; 3,244, with 1,067,760 sittings, to the Independents; 2,789, with 752,313 sittings, to the Baptists; 371, with 91,539 sittings, to sittings, to the Baptists; 371, with 91,599 sittings, to the Quakers; 1,194, with 2,444,976 sittings, to the various sections of Methodists; 570, with 186,111 sittings, to the Roman Catholics; 229, with 68,554 sittings, to the Unitarians; 222, with 30,783 sittings, to the Latter-Day Saints; 32, with 7,437 sittings, to the Catholic and Apostolic Church; and 53, with 8,438 sittings, to the Jews. The most numerous body of dissenters in Scotland, is the Free Church, which second from the established church in 1843 and is people. ceded from the established church in 1843, and is nearly, if not quite, as numerous as the establishment. They, however, disclaim the name of dissenters, as they maintain that they do not dissent from the principles of the Church of Scotland, but came out in consequence of their adherence to them. Next to the Free, is what is termed the United Presbyterian Church, which originated in the secession of a considerable body of ministers and laymen from the established church in 1732. In 1847 this body became united with the Relief Church, a somewhat later secession, under the designation of the United Presbyterian Church. According to the census of 1851, the total number of places of worship in Scotland was 3,395, with 1,834,805 sittings; of which 1,183 places of worship and 77,089 sittings belonged to the established church. Of the rest, 889, with 485,355 sittings, belonged to the Free Church; 465, with 288,100 sittings, to the United Presbyterian; 192, with 76,342 sittings, to the Independents; 134, with 40,022 sittings, to the Episcopalians; 117, with 52,766 sittings, to the Roman Catholics; and 119, with 52,769 sittings, to the noman cannoies; and 110, with 26,086 sittings, to the Baptists. The proportion of unoccupied sittings is largest in the established, and smallest in the Free Church. Dissent, at least as based upon any material point, is much less prevalent in Scotland than in England; the differences between the two principal sects of dissenters and the catablished change haing mainly regarding the connection between church being mainly regarding the connection between church and state. In Freland, exclusive of the Roman Catholics, the principal dissenters are the Presbyterians, who are mostly confined to the province of Ulster. A particular account of the different sects referred to in this article will be given under their own

heads in other parts of this work.

DISSIDENTS, dis-se-dents (Lat. dissidee, 1 disagree), is a term synonymous with our dissenters, and the term usually applied to certain sects in Poland who dissented from the Roman Catholic church, but who were yet allowed the free exercise of their own worship. Even during the lifetime of Luther, Protestant principles had made such progress in Poland that half the senate, and more than half of the nobility, had the senate, and more than half of the nobility, had adopted the new faith. The compact of Sandomir in garded as the termination of the Christmas sports.

1570 united the Lutherana, Calvinists, and Bohemian Brethren into one body (a union which had also a political tendency); and by the religious peace sworn to by the king in 1573, they obtained the same rights with the Roman Catholics. From dissensions among themselves, however, and the increasing power of the Catholic church, the dissidents by degrees lost most of their privileges, and in 1717 and 1718 they were deprived of their right of voting in the diet. In 1736, at the diet of Pacification an old statute was revived. the diet of Pacification, an old statute was revived. which required that every king be of the Catholic church. After the accession of the last king, Stanilaus Poniatowski, the dissidents brought their grievances before the diet in 1766, and were supported by Russia, Prussia, and England; Russia in particular improved the opportunity to extend her influence in Poland, and suggested by the Americanian in brigging Poland, and succeeded by her mediation in bringing about a new convention in 1767, by which they were again placed on an equal footing with the Roman Catholics; the war, however, against the confederates breaking out, and the kingdom being dismembered, with the adjustment of the confederates breaking out, and the kingdom being dismembered. little was effected until 1775, when the dissidents re-gained all their privileges, except the right of being cleated senators or ministers of state. Later events in that country have confirmed to the dissidents equal rights with the Roman Catholics. They include Lu-therans, Calvinists, Greeks, and Arminians, but exclude Anabaptists, Socinians, and Quakers.

DISSOLUTION, dis-so-lu'-shun (Lat. dissolutio, from dis, and solvo, I set free), a term variously applied, but in its commonest and most general sense implying the separation of the parts of a body which in the natural condition are united. The state of being lique-fled by heat or moisture is termed dissolution: thus, ice is changed from a solid into a fluid state by heat; nee is changed from a soild into a fluid state by heat; metals, again, can undergo dissolution by the action of an acid menstruum. The separation of the soul from the body is termed dissolution, or, more generally, death. (See Dearm.) Dissolution of the blood, in Med., denotes that condition of the vital fluid in which it does not readily coagulate on its cooling, out of the body, as in the case of malignant fever. Shakspere body, as in the case of malignant fever. Shakspere gives a fair illustration of the application of the term:—
"I am as subject to heat as butter; a man of continual dissolution and thaw."

DISSOLUTION OF MARRIAGE. (See DIVORCE.)
DISSOLUTION OF PARLIAMENT may be effected in three ways;—1. by the will of the sovereign, expressed either in person or by representation; 2. by the demise of the sovereign,—in which case, however, it is to continue in existence for six months after the demise, unless sooner proround or dissolved by the successor; and 3. by length of time, i.e. seven years. (See Pau-LIAMENT.)

DISSOLVING VIEWS, diz-zol'-ving (Lat. dissolvo), pictures painted upon glass, and exhibited by means of the magic lantern (which see). After one picture has been exhibited, by removing the founs, or lessening the light, the effect is rendered less distinct; then by means of another magic lautern, or a lens, a fresh slide is gradually introduced, so that one picture blends with another almost unconsciously to the spectator. The exhibition of dissolving views is usually accompanied with music, and the tunes played become louder as the light increases, which is always when the new picture gains its full distinctness.

DISSONANCE, dis'-so-mins (Fr.), in Mus., a term used to denote the effect produced from the unison of two sounds not in concordance with each other. and sixths were anciently considered as dissonances; in fact, every chord except the perfect concord is dissonant. Formerly there was an unlimited number of dissonances, but they are at present reduced to a comparatively small number.

DISSYLLABLE, dis'-sil-id-bl (Gr. dissullabos), in Gram, is a word of two syllables; as, goodness, brauty, DISTAYP, dis'-tiff (Sax. distaf), the staff of a spinning-wheel, to which a bunch of flax or tow is attached,

and from which the thread is drawn. Before the introduction of machinery for the purpose of spinning threads, the distaff was much used, but it is now,

### Distance

Herrick, in his "Hesperides," thus quaintly describes he boisterous mirth that marked this season:—

" Partly worke, and partly playe, You must on St. Distaff Day. From the plough soone free your teame, Then come home and fother them. If the maides a spinning goe, Burne the flax and fire the tow; Scorch their plackets, but bewars That ye singe no maiden's baire. Bring in pales of water, then Let the maides bewash the men. Give St. Distaff all the right, Then bid Christmas-sport good night. And next morrow, every one To his own vocation."

DISTANCE, dis'-tons (Lat. distare), in Paint., an expression used to denote the utmost extent to which the nower of vision can reach, or the limit of view. Extreme distance is the visible horizon of the observer, in which the land and sky appear to meet; and middle distance is that part which lies midway between the distance of the picture and the foreground. Distance, in Horse-racing, is a length of 249 yards

from the winning-post. At this point is a post with a gallery running round it, capable of helding three or four persons. It is called the distance-post. When a race is run, a man is stationed at the distance-post, and is provided with a small red flag, with which he can communicate with another man at the winning-post. When the winner passes, the man at the winning-post lowers his flag, and the man at the distance-post lowers his flag at the same time. If any horse has not then arrived at the distance-post, he is said to be "distanced," and incurs penalties accordingly.

DISTEMPRE, dis-tem'-per (Fr. détrempe), in Paint., the name given to the colouring matter used in scenepainting, and for printing and staining paper-hangings. A mixture is made of whitening and coarse size, in the proportion of ten parts of the former to one of the latter, to which the required colour is added when it has been diluted with a little water, and brought to a consistency resembling cream. Distemper colours dry very rapidly, and should be slightly warmed before they are used. This method is sometimes used in colouring the walls of houses externally, and the interior of rooms.

DISTEMPER, a disease to which young dogs are liable. It is supposed to have been derived from France, and is considered to be a typhoid inflammation ing the upper air-passages. It closely resembles the strangles of young horses, and the scarlatina and suchlike diseases to which young children are liable. The disease is contagious, occurs generally only once in a lifetime, runs a definite course, and is accompanied by low fever and debility. Careful attention to nursing and diet constitutes the most successful treatment of this disorder. A dog with the distemper is easily recognized. The eyes become red, weak, and warecognized. The eyes become red, weak, and watery; the nose hot and dry; any movement in the nir excites a cough or snezze; and there is a general dulness, fever, and loss of appetite. The running from the nose, as the disease proceeds, becomes, after some days or weeks, mucous or purulent, londing the eyes and obstructing the nostrils. It then lodges in the bronchial tubes, preventing the free access of air and the purification of the blood. All dogs are subject to distemper; but highly-bred, delicate, and fancy dogs are most liable to the disease, and the mortality amongst them is the greatest. In the cure of distemper all irritating and reducing remedies must be avoided. If the stomach is overloaded, it should be relieved by a mild emetic; and if no effect is proavoided. It has stomed is overloade, it should be relieved by a mild emetic; and if no effect is produced by the dose, it should be repeated in twenty minutes. To ward off distemper, young dogs should be very liberally and nutritiously fed. In such cases, in spite of all cure, if they are attacked with distemper, they are almost certain to pass over it very favourably. Nothing proves the prophylactic effect of pure air and voluntary exercise more than that young hounds at their walks are seldom attacked by distemper. Dogs are liable to distamper more than once; but the repetition is of unusual occurrence. Inflammation of the lungs is often the consequence of distemper; and the bowels

### Distilled Water

are always more or less affected by diarrhos and dysenteric discharges, often indicating ulceration of the intestinal canal. Protracted cases of distension are sometimes attended by a pustular eruption on the chest and abdomen, accompanied by an hepatic affec-tion usually called "the yellow disease," from its giving the whole surface of the skin a yellowish colour. The symptoms in such cases are generally fatal. Dis-temper is communicated by contact of the diseased catarrhal secretion. Inoculation has been proposed as a mitigation of the disease; but it has been proved by Mr. Blaine that vaccination is inefficacious. (See Blaine's Cunine Pathology, and Rural Sports, part iv.

Chap. iv.—Diseases of Dogs.)

DISTICE, dis'-tik (Gr. distiction, consisting of two rows), a couple of verses or poetic lines making complete sense. The term is principally applied to the lexameters and pentameters used among the Romans, especially by Orid and Catulius. Among the Greeks and Romans the distich was used as a vehicle for the expression of definite sentiments, and especially for epigram. Goethe and Schiller, together with other great poets of Germany, have, in later years, shown a great predilection for the distich, and great skill in using it.

DISTILLATION, dis-til-lai'-shun (Lat. distillo, from dis, and stillo, I drop), the process of evaporating a fluid by means of heat, and afterwards condensing it into a liquid. Its object is to separate one substance from others with which it may be mixed; and the possibility as to whether a substance can be distilled depends upon the temperature at which it evaporates. In chemistry, distillation is performed by means of a retort or flask, and a receiver. It is, however, carried on in the most extensive scale for the production or ardent spirits. It is not known when distilled spirits were first made; but the discovery is usually attributed. to the alchemists, who called it aqua vita. Originally spirits were distilled from wine; hence the common name of alcohol—spirits of wine. In the production of ardent spirits, there are two distinct operations: first, the conversion of some vegetable substance into alcohol; and second, the separation of the alcohol from the substances with which it is mixed. The latter operation is, properly speaking, distillation; although, in ordinary language, both are classed under that head. Sugar, and starch, which is easily converted into sugar, are the chief sources of alcohol. By the action of fermentation, sugar is converted into alcohol and cartermentation, sugar is converted into account and car-bonic acid; so that all substances containing sugar or starch will yield spirits after distillation. After the wash, or alcoholic mixture, has been formed, the pro-cess is continued in a still or alembic. When heated to 176°, the alcohol, mixed with steam, evaporates, and, passing through the worm of the still, is cooled and condensed, and trickles out in a liquid form into a receiver. Anhydrous alcohol cannot be obtained by distillation alone. Spirits of wine, or rectified spirit, contains as much as 25 per cent. of water. Taking water as 1000, the specific gravity of alcohol is 793. Proof spirit is the legal standard of strength established by the excise of Great Britain: its specific gravity is the exoise of Great Britain: its specific gravity is 918°6; it contains about equal parts of water and alcohol. The principal spirits obtained by distillation are,—brandy from wine, rum from molasses, and whiskey, gin, &c., from corn or malt. Among the Dutch the corn spirit is flavoured with juniper-leaves; hence the names gin, genera, from the French genierer, juniper. The Germans distil spirit from potatoes.

DISTILLATION, DESTRUCTIVE, the process of heating vegetable and animal substances in closed vessels to such a temperature as to decompose them. The results of the decomposition are collected and obtained in various ways. When coal is subjected to destructive various ways. When coal is subjected to destructive distillation, the results are gas, coke, tar, naphths, &c.; when wood is thus distilled, the results are wood-spirit, when wood is thus distilled, the results are wood-spirit, when we would be a subjected to destructive and the subject of destructive and the subject of the subject of

when wood is thus distilled, the results are wood-spirit, wood-vinegar, charcoal, &c. The results of destructive distillation are mostly obtained by condensation.

DISTILLED WATER, distild:—When water is subjected to the process of distillation, the result is abuild without odour or colour, with an insipid taste. In this form it is called distilled water, and, if evaporated to dryness, ought to leave no residue. Distilled water, in its purest possible form, is absolutely necessary to the chemis in his laboratory. (See WARER.)

### Distilled Waters

DISTILLED WATERS.—When aromatic plants are distilled along with water, the combined results are usually called distilled waters. Rose-water and larenderwater are examples of common occurrence.

water are examples of common occurrence.

DISTILLERY, dis-tile-eve, the building or works where distillation is carried on. (See DISTILLATION, STILL.)

DISTORTION, dis-tole-ekan (Lat. distortio, from dis-lorgueo, I twist), in Surg., is a permanent deviation from the natural shape or position of the body, producing visible deformity. Distortions may arise from various causes. They generally occur after birth, and thus differ from deformities, which are for the most part congenital. Distortions are frequently occasioned by affections of the muscles or nerves. It is well known that every movable part of the body is furnished with two sets of muscles acting in contrary directions, by two sets of muscles acting in contrary directions, by means of which it is not only moved, but also retained in its natural position. Hence it is evident that if, by means of any injury to one of the sets of muscles, means of any injury to one of the sets of muscles, or of the nerves communicating with them, their contractility is destroyed or impaired, the part can no longer be maintained in its natural position, but will be drawn towards the antagonistic muscles. In this way various kinds of lameness, wry neck, squinting, &c., are produced. The most common cause of distortion, however, is disease of the bones. These are sometimes deficient in the earthy matter which gives them hardness and rigidity, and thus are incapable of sunhardness and rigidity, and thus are incapable of sup-porting the weight of the parts which they are designed to bear, or of sustaining the muscular action, without becoming bent and distorted. From this arises the disease known as rickets (which see). The distortion known as the lateral curvature of the spine arises from weakness in the vertebral muscles, inducing a habit of weakness in the vertebrai muscles, inducing a habit of resting the weight of the body more on one side than the other. Unlike rickets, which commence early, this does not usually make its sppearance before the tenth year, and is most commonly found among slender and delicate females in the higher and middle ranks of life. It is generally occasioned by too much confine-ment and externit occasioned by too much confinement and restraint, and is best got rid of by plenty of free exercise of the limbs in the open sir. Angular curvature of the spine differs entirely from the above, and is occasioned for the most part, by ulceration of the body of one or more of the vertebræ. The support in front being thus lost, the spine is bent sharply forwards, and one or more of the spinous processes project behind. Perfect rest in the horizontal position, issues and setons in the neighbourhood of the diseased bone, and attention to the general health, is the treatment to be adopted in this case. Diseases of a similar kind frequently occur in the bones and joints of other parts of the body, and require similar treatment. Distortions may also arise from a variety of other causes; as rheumatism, gout, burns, and various chronic and local affections; but these come more properly for consideration under their own heads.

DISTORTION, in Phot., a term applied to the unnatural increase in size of certain parts of the picture. Distortion arises from several causes; such as using too small a lens; not using a sufficiently large diaphragm

small a lens; not using a sufficiently large disphragm or stop; by approaching the object too closely; or by the lens itself being improperly connected.

DISTRESS, dis-trees' (Lat. districtio), in Law, is the taking of a personal chattel out of the possession of a wrong-doer into the custody of the party injured, to procure satisfaction for the wrong committed. Districts of the procure of the form of the procure of the procure of the form of the procure of the form of the procure of the pro tresses are either for some duty omitted, some default, or nonfeasance; or they are in respect of some wrongful act done by the distraince. The most usual injury for which a distress is taken, is that of non-payment of rent. A lord may also distrain of common right for neglect to do suit to the lord's court, or other certain persons service. Distresses may also be taken where a man fluds beasts of a stranger wandering in his grounds doing him hurt or damage; in which case the owner of the soil may distrain them while they are upon his grounds, till satisfaction be made to him for the injury he has sustained. As a general rule, all chattels personal are liable to be distrained, unless

## Distribution of Animals

generally speaking, whatever goods or chattels the landlord finds upon the premises, whether they, in fact, belong to the tenant or a stranger, are distrainable by him for rent, the stranger having his remedy by action on the case against the tenant. Fixtures, however, and things in the custody of the law, money (except in certain cases), and goods of a perishable nature, as fruits, milk, &c., are exempt from distraint; as are also beasts of the plough, and the instruments of a man's trade or profession, if there be sufficient property on the premises otherwise. A distress cannot be made in the night except in the case of oattle damage forward, as otherwise they might escape. A landlord may distrain within six calendar months after the determination of the lease, provided his own title or interest, as well as the tenant's possession, continue at the time of the distress. In general the distress must be made on the premises; but goods fraudulently or clandestinely carried off may be distrained within thirty days thereafter, unless they have been bond fide sold for a valuable consideration. The landlord may not break open a house of which the rent is in arrear to make a distress; house of which the frent is in arrear to mean a minute on but when he is in the house, he may break open an inner door. Distresses must be proportioned to the thing distrained for, and an inventory of as many goods as are judged sufficient to cover the rent and expenses, must be made and served personally on the tenant, together with a notice of the fact of the distress having been made, and the time when the rent and charges must be paid, or the goods replevied. The landlord cannot seil the goods distrained before the expiry of tive days; and prior to the sale, an appraisement must be made by two sworn appraisers of the value of the goods. After the sale, it there be any overplus after payment of the rent and expenses, it is to be handed over to the tenant. Cattle cannot be lawfully distrained if found trespassing through default of the occupier of the land by neglecting to repair his fences or to shut his gates, unless the owner of the cattle suffer them to remain after receiving notice of their trespass; neither can they be distrained if once off the land upon which

they have been trespassing.
DISTRIBUTION, dis-trib-w-shun (Lat. distribuo, I distribute), is the placing particular things in the places or compartments which have been already prepared to receive them. In Log., a term is said to be distributed when it is employed in its full extent, so as to comprehend everything to which it is applicable; to be spread, as it were, over the whole class, and applied to each object individually, not to all collectively. When a common term denotes fewer than all the objects of a class, it is said to be taken particularly, or to be undis-

DISTRIBUTION OF ANIMALS .- Certain tribes, genera, and species of animals are peculiar to certain portions of the globe. In some respects the distribution of animals resembles that of plants, and both these are dependent on meteorology. Thus, where vegeare dependent on meteorology. Thus, where vege-tation is most abundant, animal life is most prolific. Plants are stimulated in their growth by heat and moisture; and as in tropical climates the heat and moisture are greatest, there also the animal formations are most abundant. As they decrease in a direction from the equator to the poles in perhaps a similar proportion, so do animals decrease, not only in the size of individuals, but in the number of species. This law affects vertebrate and invertebrate animals which inhabit the land, but is reversed in the case of those animals of higher organization which inhabit the sea. The latter are found to increase in a direction from the equator to the poles. The distribution of animals is also limited in many cases by the intervention of seas or lofty ranges of mountains; but animals, like plants, are salapted to particular climatic conditions, and, like them, are subject to fixed laws. Man can endure the scorehing heat of the tropic zone and the intense cold of the Arctic circle. The dog, however, is the only vertebrate animal that can accompany him. Many animals cannot exist except in a determined climate, The iton and tiger would soon die in an arctic climate, and a polar bear could not exist at the tropics. In specially protected or exempted, as are all animals and a polar hear could not exist at the tropics. In fere nature; whatever is in the personal use or occupation of any man at the time; and things delivered portion as the observer recedes from the coast. Certoa person exercising a public trade, to be carried, tain species of animals remain shut up in a chain of wrought, or managed in the ways if his trade. But, mountains, and are unable to move to other similar

# Distribution of Wealth

localities; for, as the temperature decreases with the elevation, before they could pass to another mountain-ridge they would have to traverse a region whose temperature would be much higher than that to which they are accustomed. The Himslayan Mountains thus present to the ascending traveller a succession of species similar to that met with in travelling from Brazil to Labrador, or from India to Kamtechatka.—

BISTRIBUTION OF WEALTH. (See WRALTH, DISTRIBUTION OF WEALTH.

BUTTON OR )

DISTRIBUTIONS, STATUTE OF, is the name given to statute 22 & 23 Car. II. c. 10, explained by 29 Car. II. c. 3, which regulates in England the division of the c. 3, which regulates in England the division of the estate of a person dying intestate. It enacts, that after the expiration of one full year from the death of the intestate, one-third of the surplus of his personal estate shall go to the widow, and the remainder be divided in equal proportions among the children. If there be no children, then the widow is to have one half, and the other half to be divided among the nearest of kin; if no widow, then the whole to go to the children; and if neither widow nor children, then the whole to

be distributed among the next of kin.

District, dis'-trikt (Lat. districtus), in general language, a limited extent of country, or a circuit within which right or authority may be exercised. Military districts are portions of Great Britain which are set apart in order to assist military command. and organization. Each district has its head-quarters at some particular town. The northern district of England has its head-quarters at Rotherham, the western at Plymouth, and the south-western at Ports-mouth. London is the head-quarters of the rest of

England, which is considered to be a military district, Edinburgh is the head-quarters of the Scottish district; and Ireland is divided into five districts, the headquarters of which are Dublin, Cork, Limerick, Athlone, and Armagh.

and Armaga.

Diren, dith (Sax. dic), in Agr., a long trench cut by the sides of roads and fields, to carry off the surplus water that may fall on the surface. When land is drained by means of pipes, these discharge themselves into a ditch dug along the lowest side of the field. In flat low countries the fields are often separated by broad ditches, without any other kind of fence whatever. The banks of these are sometimes planted, and the field is entered through a gate placed on a bridge thrown across the ditch, and wide enough to admit of the passage of a cart. Where it is practica-ble to do so, the earth taken from the ditch is formed into a bank and planted with thorns, which in a few years form an impenetrable fence.

years form an impresentation rate.

Dirox, in Mil., a broad and deep trench surrounding
the rampart of any fortification. The rampart is generally formed of earth taken out of the ditch. The main ditch of a fortress is about 120 feet wide and 12 feet below the level of the ground. The sides are generally secured with revetments of masoury. The side immediately below the parapet is called the scarp of the ditch, and the side opposite to the scarp is called the

counterscarp.

DITHIONIC ACID, dith e-on'-ik, in Chem., SoOs: also called hyposulphuric acid, - the second of the thionic

called hyposulphuric acid,—the second of the thionic series of sulphuric and oxygen compounds, all of which contain five equivalents of the latter. It unites with transforming salts, generally known as hyposulphutes, none of which are of any importance.

DITHYRAMBUS, dith-e-rdm'-bus (Gr.), a surname of Bacchus. In ancient verse, the term was used to designate a species of lyric poetry, more particularly cultivated at Athens. It was distinguished by its wildness and enthusiasm, but in later years it degenerated into mere bombast. Originally the dithyrambus was a hymn sung in honour of the deity after degenerated into mere bombast. Originally the dithyrambus was a hymn sung in honour of the deity after
which it was named. It was generally sung by a
chorus of fifty, who danced in a circle as they sang
round the blazing altar of the god. The song was at
first rudely accompanied by flute-music, but afterwards Arion invented a regular choral form for it.

Dirro, distric (Lat. dictus, said), a term in common
use, signifying aforesaid, or the same thing. The derivation of the term is more directly from the Italian
defice, it is need to save repetition and is often con-

detto; it is used to save repetition, and is often contracted to the form de.

Divers

DITTY, dit'-te, a term derived from the Latin dictum-It was originally spelt dittie, and implied in its primi-tive sense a saying or sentence. In modern times, however, it has been used to signify a short poem or

DIURETICS, di-u-ret'-iks (Gr. diouretikos), in Meda-those agents which have the power of augmenting the secretion of urine. Their action is beneficial whenever the system is troubled with an excess of fluids or of salts and nitrogenous substances derived from effete salts and nitrogenous substances derived from effectissues. There are some diureties, such as nitrate of potash, which act primarily upon the urinary organs; others, as the mercurials, which act primarily on the absorbents and secondarily on the kidneys; and others again which act directly on the urinary organs. Stimulant and tonic medicines have generally a diuretic action in cases of debility. As in the case of the function of perspiration (see Diaprometros), so in that of the secretion of urine, many external circumstances influence its due performance. These two erreat functions seem to supply the place of, and alterstances influence its due performance. These two great functions seem to supply the place of, and alter-nate with, each other, and the circumstances which favour the one will generally interfere with the other. To secure the proper action of a disphoretic, the skin of the patient must be kept warm: but, in employing a diuretic, it is necessary to keep the skin cool.

Divan, div-an', an Arabic or Persian word, originally signifying a register of names and accounts, but more

signifying a register of names and accounts, our more generally employed to designate a court of justice or supreme judicial tribunal. The word, however, is very variously applied. Among the Persians, a collection of poems or songs by one and the same author is called a divan. The state or reception rooms in palaces and the prints because of the rich gitterns of Constantithe private house of the rich citizens of Constanti-nople are also called divens. Among Europeans the term is more generally applied to a kind of soft, probably from such being used in the divens of the orientals. Cigar divans are establishments fitted up with couches, &c., where, by paying a fee, visitors can smoke, read the periodicals of the day, and be pro-

vided with coffee and other refreshments.

DIVELON-THE-NECK, div.el, an instrument of tor-ture, employed against the Lollards. Fox, in his "Acts and Monuments," thus describes it:—"Certain strait irons, called the divel-on-his-neck, being after an horrible sort devised, straitening and winching in the neck of a man with his legs together, in such sort as the more he stirreth in it the straiter it presseth him, so that within three or four bours it breaketh and crusheth a man's back and body in pieces."

Diverging Lives, di-eerf-ing (Lat. diverge, I tend from), a term employed in Math. and Opt. to denote those lines which separate or recede from one another after proceeding originally from the same point. Diverging lines are opposed to converging lines. a convex lens renders the rays of light convergent, while a concave lens renders them divergent. In Math., a diverging series is one of which the terms in-

crease more and more the further it is continued.

Divers, di-verz (Mergus).—The divers closely resemble the grebes; indeed, the chief point of difference consists in the former having palmated feet. They have a strong, straight, rather compressed, pointed bill, about as long as the head; a short rounded tail; short wings; their legs placed far back, and toes completely webbed. They fly well, and, as divers, are remarkably expert. They measure usually from two and a half feet to three feet in length, and are essentially inhabitants of high northern istitudes, visiting our shores in the autum, remaining through the winter, and quitting us in the spring to seek their northern breading-stations. The great northern diver (Colymbus glacialis) is the largest of the tribe. It measures full three feet in length, and four feet six inches in breadth. The bill, which is black and very strong, measures four inches from the top to the corners of the meuth. The head and neck are black, shaded with purple and green. At the back of the neck there is a white crescent-shaped band, marked with black oblong strokes pointing downwards. The breast and underside of the body are white; the back, wing-coverts, and scapulars, are black, thickly dotted with white. Speaking of this bird, Dr. Richardson says, "It can swim with great swiftness; and to a very considerable distance, under water; and when it feet in length, and are essentially inhabitants of high

comes to the surface, it reidem exposes more than the neck. It takes wing with difficulty, dies heavily, though swiftly, and frequently in a sixele round those who intrude on its haunts. Its load and very melancholy cry, like the howing of the wolf, and at times like the distant screams of a man in distress, is said to portend rain. Its flesh is dark, trough, and suppaistable." The red-throated diver (Cospuden septentrionals) is smaller than the great northern, and lighter coloured. In habitat, however, they exactly agree.

Diving the great northern, and lighter coloured. In habitat, however, they exactly agree.

Diving the great northern, and lighter coloured and the great northern would be a short, light, pleaning supposition, vocal or instrumental, written in a style calculated to engage the popular ear. Divinguing, div-e-dend (from Lat. divide, I separate), in Com., is applied either to the money which is divided amongst the oreditors of a bankrupt out of his estate, or to the annual interest payable upon the national

or to the annual interest payable upon the national

debt and other public funds.

Divination, dic'dn-a'-shin (Lat. divinatio), a term applied generally to the various arts used in all ages for the discovery of things, secret or future, in a supernatural way. In all ages, and among all nations, there has been exhibited a strange feeling of curiosity which has prompted mankind to look forward into tuturity with the intention of penetrating its mysteries. Ori-ginally, these speculations were made by deep thought, by comparing the past with the present, and by drawing careful inferences as to the probable course of events. The human mind did not, however, stop at this point, for the strong desire to look into futurity led mankind to see presses of events in things be-tween which and the object of anxiety no connection existed whatever. Every department of nature began to be consulted, as furnishing good or bad omens of human destiny. The feeling among ancient nations was, that if gods really existed, they cared for men; and if they cared for men, it was only natural that they should send them signs of their will. From this sentiment divination began to form a regular science, intimately allied to religion, and furnished with particular laws and regulations, differing in character according to the degree of civilization attained by the country in which it was established. Among the ancient Greeks and Romans, divination was practised with great enthusiasm. In the most trivial matters with great enthusiasm. In the most trivial matters of every-day life they saw something that had reference to the future, or destiny, while their auguries and oracles formed the higher class of divination. The different systems of divination employed by the ancients are very numerous. Aëromancy, or divining by the air; Arithmomancy, or divining by means of numbers; Capnomancy, by the smoke of sacrifices; Chiromancy, by the lines in the palms of the hands; Hydromancy, by water; Pyromancy, by fire, &c., constitute only a few of the many methods in vogue. A number of superstitious customs in use at the pre-A number of superstitious customs in use at the present day evidently owe their origin to ancient forms of divination. Lucky and unlucky days were once considered very important matters of consideration; and even now, in commencing any undertaking, Friday is avoided by many persons in all ranks of society. It is also generally conceived that a wedding in May is unlucky. A large number of omens are associated with lucky. A large number of omens are associated with what first happens to any one about to undertake anything. To stamble is always considered unlucky; various lucky and unlucky signs are deduced from the number of certain hirds-generally mappies—seen. A hare excessing the path is deemed unlucky; so is an old woman. Priests were formerly considered unlucky, and the hunters of old, when they met a priest, coupled up their hounds and retired; there was no sport for them on that day. Many superstitions of this kind are associated with the subject of love and the subject. The variable and unaccountable changes. marriage. The variable and unaccountable changes and chances connected with the subtle passion no doubt fostered these, and people drew conclusions from the most improbable sources. The methods by from the most improvate source. The meaning of which people even yet endeavour to foretell a future husband or wife—happiness or misery—are innumerable. These customs vary in different localities, and are often restricted to certain days; such as the eve of

St. Ages or Hallows'en, the last night of October.

St. Ages or Hallows'en, the last night of October.

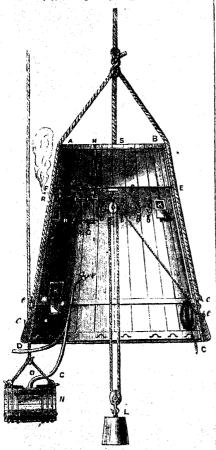

Drving Right, divined (Lat. divinus), in Pol., a term applicated to denote the scarce of kingly power, and formerly used as an argument to maintain the

claim of monarchs to absolute and unqualified obedi since from their subjects. The monarch was held to be the direct representative of Daily, to whom alone he was responsible for his actions. This subject gave rise to much controversy in England during the strug-gle between the Royalets and the Parliament, the former of whom stood up for the divine right. Some traced this divine right to the primitive patriarchs away, which was the true Scriptural idea; others to some supposed social contract, in which men gave up their natural rights in exchange for protection. The present king of Prussia, at his coronation recently excited some surprise by asserting the doctrine of the divine right of kings. divine right of kings

DIVINE SERVICE, in Law, is applied to an obsolete mode of tenure, in which the tenants were obliged to perform some special divine service; as to sing st many masses, distribute a certain sum in sims, &c.

many masses, distribute a certain sum in sums, acc.
Diving-Iblut, d'ving (Sax. dyfon, to dive), a vessel,
generally made of cast iron, by means of which persons
can descend to a great depth under water, with slight
inconvenience. It was probably invented about the
16th century. In the time of Aristotle, divers used a
kind of kettle; but the manner in which it was used in
the depth of the control of the contr not clearly described. In 1538, a diving-bell was used by two Greeks at Toledo, in Spain. In shape this vessel appears to have been very like that of the modern diving bell. The experimentalists let them-selves down under water, with a burning light inside the hell, and rose up again without being wet, and with the light still burning. The art was then new; for, according to John Taisnier, the experiment was witnessed by Charles V. and a multitude of spectators, in order to test its possibility. After the destruction of the Spanish armada, many of the ships were sunk of the island of Mull, on the western coast of Scotland. The Spanish prisoners had declared that these vesse's coutsined great riches; and this report excited much contained great riches; and this report exerted macina avarice, and tempted speculators to endeavour to gain the lost treasure. In one of these attempts, made in 1665, a rough kind of diving-bell was used, but not successfully. In 1687, a person named Phipps, under the patronage of the duke of Albemarle, formed a district formed a few patronages. the patronage of the duke of Alcelharic, formed a project for searching and unloading a Spanish vessel sunk on the coast of Hispaniola. He descended by means of a diving-bell, and returned to England with £200,000, which he had gathered from the wrsck. Dr. Halley's bell was the first really practical and useful diving-bell. It was made of wood coasted with lead, and contained about 60 cubic feet of air. It was made in the form of a truncated cone, three feet in diameter at the top and five feet in diameter at the base. In the top a clear glass was inserted, to let in the light. For the purpose of introducing fresh sir, two barrels lined with lead were sunk alongside the bell. They were provided with hose and taps commu-nicating with the interior of the bell. The pressure of the water forced the air, when required, into the vessel, and the impure air was allowed to escape through a valve in the top. In 1721 Dr. Halley's diving-bell was improved by an additional apparatus designed by himself, and by means of which the diver was able to leave the bell at some distance, and remain a considerable time in the sea. The man was supplied with air by means of a large metal helmet with glass symboles. It was supplied with air from the bell by means of facible tubes. Several ingenious improvements have been made upon Halley's diving-bell at various times, the most important of which means of peen made upon Halley's diving-bell at various times, the most important of which, perhaps, are those of Smeaton, who first applied the bell to operations of engineering. To Smeaton also belongs the invention of the modern cast-iron diving-bell. The first bell of this sort was used in the formation of Ramagnte harbour, in 1788; it weighed 50 cwt. The men inside the bell being powerless as to its motions, are obliged to communicate by means of signals with those above. On account of the facility with which water transmits On account of the facility with which water transmits aboud, a stroke on the side of the bell can be easily heard by those on the surface. Taking advantage of this circumstance, it is generally arranged that one stroke means "more act," or "pump strong;" two strokes, "stand fast;" three, "hoist;" four, "lower; "five, "more south;" six, "north;" seren, "front;" eight, "back;" nine, "lower down the bucket;" ten, the length leaded for health of the length le On account of the facility with which water fransmits "hoist up the bucket loaded, &c. At Plates XLII

and XLIII., as well as in the accompanying engravings, we give various forms of diving apparatus, from that invented by Dr. Halley to the latest and most approved invented by Dr. Halley to the latest and most approved forms, wiz, the invention of Mr. Heinke, and another called "the Nantilum." Fig. 1 Plate XLII., shows a sectional view of Dr. Halley's diving-bell, one of the air-barrels, and the appearing for enabling the diver to leave the bell. This diving-bell was of wood cased with lead, three feet wide at top, five feet at bottom, and eight feet high. In the top was fixed a meniscus quass (D) to let in light from above; there was a tap at B to let out the hot air; L M was a circular seat for the diver to sit down upon. The supply of sir to this hell when under water was provided from a couple this bell when under water was provided from a couple of barrels (C), holding thirty-six gallons each. These

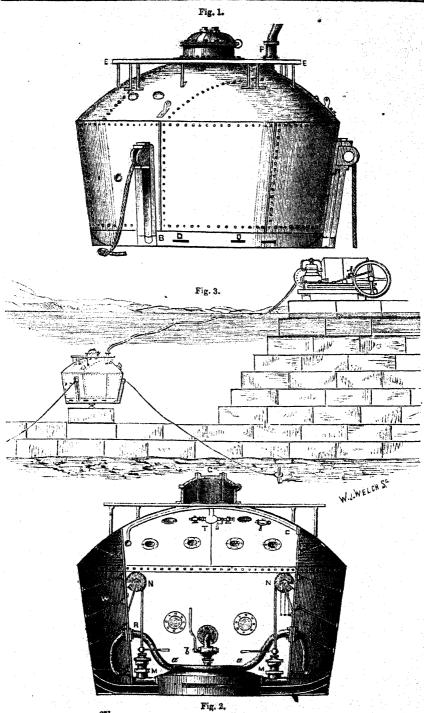

SPALDING'S DIVING-BELL.

air-barrels were provided with tackle to cause them to rise and fall alternately. In the accompanying fig. is exhibited a sectional view of Spalding's divinging is exhibited a sectional view of Spalding's diving-bell. A B C D is a section of this bell; c, c are iron hooks, by means of which it is suspended by ropes (Q, B, E, c, and Q, A, F, E, c) joining at Q; c, c are iron hooks, to which are appended leaden weights for the purpose of keeping the mouth of the bell always parallel to the sufface of the water. By these weights alone, however, the bell would not sink; another is therefore added, represented at L, which can by essaed and lowered at heleasure by means of

sides of the ball. As the bell descends, this h sides of the bell. As one bell ascentifi, and season-weight hange down a considerable way below the mouth of the bell. In case the edge of the bell is caught by any obstacle, the balance-weight is imme-diately lowered down, so that it may rest upon the bottom; by this means the bell is lightened, so that bottom: by this means the bell is lightened, so that all danger from oversetting is removed. By an ingenious contrivance it was possible to raise this bell, with all the weights appended, to the surface, or to stop at any particular depth; and thus they would still be safe even if the rope designed for raising the bell were broken. For this purpose the bell was divided into two compartments, each of which was made as tight as possible. Just above the second bottom (E, F) are small slits in the sides of the bell, through which the water, entering as the bell descends, displaces the air originally contained in the compartment, which goes out at the orilles H. When this is done, the divers turn a handle which stops the cock, so that if any more air enters the compartment A E FB, it could no longer be discharged through the orilles H as before. When this compartment is full of water, the bell sinks; but when a considerable oridee H as before. When this compartment is full of water, the bell sinks; but when a considerable quantity of air is admitted, it rises. If, therefore, the divers desire to rise, they turn the small cook I, by which a communication is opened between the upper which a communication is opened, between the upper and lower compartments of the machine; the conse-quence of this is that a quantity of air immediately enters the upper compartment, forces out a quantity of water contained in it, and thus renders the bell lighter by the whole weight of the water which is thus displaced. N represents an air-cask with its tackle, and C I' the flexible pipe through which the sir is admitted to the bell. It is a small cock by which the mitted to the bell. It is a small cock by which the hot air is discharged as often as it becomes trouble-some. One of the most ingenious of the many machines devised to answer the same purpose as the diving-bell was that invented by Mr. Rowe. At Ig. 2, Plate X Li I., is given a view of this machine. It was a trunk or hollow vessel of copper or brass, of sufficient strength to resist the pressure of deep waters. It was designed to contain the body of a man, supposed to enter therein feet foremost, at A A, bent at the bearing of his knees at B. At A, a, and on the other side, were holes for his arms to pass through, and a glass to see through at b; d represents a sleeve made of soft leather, and featened to the body of the machine at a; A A represents a cover to fit the head of the machine, fastened down with screws, so as to prevent leakage in any depth of water; D represents a plate of lead to act as a weight to sink the machine, as well as to form a balance thereto; g is the rope by which the apparatus is let down and hauled up from the bottom; h is called the life-line, with a knot at t, so that the handle at f may always remain at a due distance for the diver to take hold of, in order to signal those above. At E and F are two brass screws, the caps of which are onened as soon as the diver rises and a glass to see through at a; d represents a sleeve the caps of which are opened as soon as the diver rises the caps of which are opened as soon as the diver rises to the water's surface, to supply him with freah air; H H is a rope, to which the diver fastens anything to be brought up. Klingert's diving-machine is shown fully equipped according to this method. It was constructed of strong tin plate in the form of a cylinder, and was placed over the head and body of the diver, leaving the legs and arms free. Fig. 4, Plate XLII., exhibits a sentional drawing of Triewald's diving-bell, which machine (A B) since with leaden which the CDD. which machine (AB) sinks with leaden weights (DD), suspended from the bottom of it. It was made of copper throughout the inside; three strong convex lenses, only two of which (G, G) are seen, defended by copper lids (H, H), illuminated this machine. The iron plate E served the diver to stand upon when at work. This is suspended by chains (F, F) at such a distance from the bottom of the bell, that when the diver stood upright, his head was just above the water in the bell, where he had the advantage of air fitter. ropes (Q, B, E, c, and Q, A, F, B, c) joining at  $Q_1$  for respiration than when he was higher up in the hell; c, c are iron hooks, to which are appended leaden when the purpose of keeping the mouth of the wights for the purpose of keeping the mouth of the always parallel to the sufface of the water. By these weights alone, however, the bell would not sink. This was affected by means of a partial copper table (b c). A most efficient and safe apparatus to can be raised and lowered at pleasure by means of a submarine operations to be conducted has been rope passing over a pulley (a), and fastened to the

has spent many years in conducting works under water. His invention consists of a diving-helmet, which is attached to a waterproof dress. A most useful adjunct is the submarine lamp, to be carried in the hand of the diver, which is also the invention of Mr. Heinke. With respect to the helmet,—upon the breastplate and in front of the diver is placed a safety breastplate and in front of the diver is placed a safety-valve, so as to be easy of sceess to the man, who can at any moment close it wholly or partially; by which means the egrees of the air fed from above can be regulated. If the diver closes this valve completely, his waterproof dress is at once inflated, and his buoyancy becomes so greet, that without an effort he rises to the surface like a cork, in a much more expeditious manner than he could climb up by the ladder, or even be drawn up by those stationed above: should any injury happen to his dress or the glass eyepiaces of his helmet be broken, the opening thus formed can be instantaneously turned into an egress-hole, and the air be driven out by this into an egress-hole, and the air be driven out by this exit, to the total exclusion of the water. This appaexit, to the total excussion of the water. This apparatus was exclusively used in the submarine works in the Westminster Bridge, when an instance of the value of the invention was given. It happened that one of the divers struck one of his glasses against a spike, and had be not closed the valve, the water would introduce that contracted and doubtless the diverse would instantly have entered, and doubtless the diver would have been drowned; but as it was, he turned the valve, instantly have antered, and doubliess the diver would have been drowned; but as it was, he turned the valve, and experienced no inconvenience: his clothes were not even wetted by the accident. At Plate XLIII., figs. 1, 2, 3, we give engravings showing a section and elevation of one of Heinke's belinets, as also a sectional view of the valve. A writer in the Mechanic's Magazine thus describes them:—"Fig. 1 shows a front elevation of the helmet itself. It will be seen from this that the openings are also provided (as an extra safety-guard) with segmental plates, so that by turning either disc round by means of the buttons which project from the circumference, the openings can be closed instantaneously. The regulating or safety valve is seen in front of the helmet, just below the joint indicated by the letter A, which joint enables the whole top of the helmet to be taken off at pleasure. Fig. 2 shows a section through the head-piece, exhibiting the pipe at the back through which the sir is fed down the valve for safety, in the event of the bursting of a feed-pipe. From the orifice will be seen the tubes extending over From the orifice will be seen the tubes extending over the upper internal surface of the helmet, for leading the stream of air over the glasses; and again below, and marked by the letter B, will be seen the safety-valve before mentioned, which can be opened or shut at pleasure by the diver. This valve is shown in section on a larger scale in fig. 3. It will there be seen that an ordinary valve, which is held in place upon its seat by means of a spiral spring, is covered with a cup perforated in the top so as to allow of the escape of such air as passes; but so fitted as to turn upon the outside of the valve-box or seat at pleasure. This is provided with a long slotted hole, which runs some distance around its circumference, and the lower part of the valve-seat or box is provided with a similar slot. From this description it will be apparent that the cup can be turned so as either to let the two holes be in one, and thus open to allow of the escape of the air, or the upper internal surface of the helmet, for leading From this description it will be apparent that the cup can be turned so as either to let the two holes be in one, and thus open to allow of the escape of the air, or be closed, should it be desired. By this simple contrivance the diver can regulate the egress of the air, and so the extent of the supply, to the greatest nicety. We must now pass on to the latest of Mr. Heinke's improvements,—his lamp. Figs. 4 and 5 show a side elevation and longitudinal section of this show as delevation and longitudina

this means the bottom surface of the sea can be examined without removing the lamp from its upright position. The lamp is also provided with two eide lenses I, I; or three can be used if required. The upper cup is fitted with an internal cone, which is connected with a pipe leading to the surface of the water for the escape of the products of combustion. This lamp gives a brilliant light, and the air supplied, percolating through the lower ring, enables it to burn steadily, a matter of considerable importance." By means of this valuable invention a diver may conduct his operations at the bottom of the sea in comparative his operations at the bottom of the sea in comparative safety. The new form of diving bell, which has re-ceived the name of "the Nautilus," has been success-fully used in the construction of the Victoria docks and in some works on the Seine. The Nautilus machine is entirely independent of suspension; its move-ments are entirely dependent on the will of those within it, and without reference to those who may be stationed without. A reference to fig. 1 will show that the form of the Nautilus is a perfectly enclosed one; hence, its displacement of water being greater than its own weight, it must float to the surface. The entrance to the machine is through a man-hole at the top. The interior is divided into chambers, which are connected at or near the bottom of a pipe  $(a \ a, \text{fig. 2})$ , which opens by a tap (b) outwards to the external surrounding water. An opening in the bottom of the machine, of variable dimensions, is closed by a door or doors susceptible of being opened or closed at pleasure. The chambers (W, W, fig. 2) are likewise connected at top by a smaller pipe (c c), which opening is affixed a flexible pipe with smaller of the machine, and to which opening is affixed a flexible pipe with coils of wire spirally enclosed. This pipe (T) has also branches communicating with the larger or working chamber. The Nautilus is supplied with air through chamber. The Nauthlus is supplied with air through the flexible pips a, fig. 2, by means of the arrangement depicted in the engraving, fig. 3. A powerful sir-condensing pump furnishes a receiver in connection with the flexible pipe a. The modus operandi studescribed in the last edition of Ure's Dict. of Arts, Mamfactures, and Mines:—"The operator with his assistants enters the machine through the top, which is then closed. To descend, the watercock (b) is opened, and the external water floweints the obsumbers W. W. at the same time a cock on a vine opening W, W; at the same time a cock on a pipe opening from the chambers outward, is opened, in order that, from the chambers outward, is opened, in order that, the air escaping, an uninterrupted flow of water may take place into the chambers. The weight of water entering the chambers causes a destruction of the buoyancy of the machine, and the Nautilius gradually sinks. As soon as it is fairly under water, in order that the descent may be quiet and without shock, the watercock b is closed. The receiver at the surface being previously charged by the air-pump to a density somewhat greater than that of the water at the depth proposed to attain, one of the branch-cocks on the pipe c c, connecting the chambers at top, is opened, and the air rushes into the working-chamber, gradually condensing, until a density equal to the density of the water without is attained; this is indicated by proper air and water gauges. These gauges marking equal points, showing the equilibrium of forces with-out and within, the cover to the bottom (z) is removed

## Divining-Rod

DIVINING-Rop, div-i'-king (Lat. divine, I divine), a hazel twig cut in the form of a y, by the aid of which certain persons, called dowsers, pretend to be able to discover water or mineral veins. The rod is held in a peculiar manner, and the dowser walks backward and forwards over the ground to be tried. As soon as he crosses or appreaches a metallic vein or aqueous spring, the twig turns towards it with a slow rotatory motion. The superstition has not yet died out, and dowsers are common in Devon and Cornwall. DIVINITY. (See TEMPLOGY.)

DIVINITY. (See THROLGGY.)
DIVINITY. (See THROLGGY.)
DIVINITY, divise-s-bit-e-fe, the property possessed by all bodies of being acparable into parts. The question as to whether matter is or is not infinitely divisible, was formerly much agitated among philosophers. According to the nature of the atomic theory, the question is not of importance to science; but, from investigation made, there seems to be no limit to the divisibility of the most solid bodies. The diffusion of colours through the atmosphere shows the minute division of material particles; and the tinging of large quantities of fluid with minute portions of colouring matter is an instance of the same. In the gilding of buttons, five grains of gold, which is applied as an amalgam with mercury, are allowed to each gross. In this way a coating is left which must amount to the urine of 13,000 feet, covered throughout its entire length with gold. In the theory of numbers, the term divisibility indicates the capability of any number being divided by another without remainder.

DIVISION, div-iz'-zhun (Lat. dividere, to divide).—In Mil., an army which is under a general officer, known as the commander-in-chief, is always divided into two or more divisions, each under the command of a general officer. Each division is again subdivided into brigades, and each brigade is composed of about four regiments or battalions. A division consists of all arms of the service,—cavalry, infantry, and artillery.
DIVISION, in Practical Mus., implies a course of notes running into each other in such a manner as to form one connected been of sounds. in Yocal Mus.

DIVISION, in Practical Mus., implies a course of notes running into each other in such a manner as to form one connected chain of sounds; in Vocal Mus. it is applied to a single syllable. The singing or playing a passage of this kind is called running a division. With theoretical musicians it signifies the divisions of

the intervals of the octave.

Division, one of the principal rules of arithmetic. By this operation can be determined how often one quantity is contained in another. There are three numbers employed in division: the first is called the divisor, the second the dividend, and the third the quotient. The dividend is the number to be divided; and the quotient. The dividend is the number to be divided; and the quotient, the result. Both divisor and quotient are factors of the dividend. Division may, therefore, be defined as the operation of finding the second factor of a given quantily when the first is given. It is divided into two classes,—arithmetical division and algebraical division. In arithmetical division, when the numbers are expressed in the scale of tens, the following is the mode of working:—On the left-hand side of the dividend, is written the divisor, separating them by a line. Beginning with the highest order of units of the dividend, the lower orders are passed over until the fewest number of figures is found that will contain the divisor; it is next determined how many times the divisor is contained in these figures, and the number is written on the other side of the dividend, beginning from the left, for the first figure of the quotient. The divisor is contained in these figures of the dividend used, and subtracted from them, and the next figure of the dividend is brought down to the remainder. The operation is contained that if all the figures of the dividend are used; the final result is the quotient. The operation is contained in the result forms the second figure of the quotient. The operation is contained in the result forms the second figure of the quotient. The operation is contained in the result forms the second figure of the quotient. The operation is contained in the result forms the second figure of the quotient. The operation is contained in the result forms the second figure of the quotient. The operation is contained in the result forms the second figure of the quotient. The operation

### Division

first reduced to simple fractions, if one or both are mixed fractions; the terms of the divisor are then inverted, and the dividend multiplied by the resulting fraction. The product is the fractional quotient, which is reduced to its lowest terms, or sometimes to a whole number, by the rules for the transformation of fractions. As an example:—Divide

 $5_2^*$  by  $2_1^*$ ;  $5_2^* = 1^*$  and  $2_1^* = 1^*$ ; hence the quotient is equal to

 $\frac{43 \times 7}{8 \times 15} = \frac{901}{120}$ 

which cannot be reduced to lower terms. In the division of decimal fractions, the dividend and divisor are written down as whole numbers, as many 0's being added to the dividend as may be necessary. The diviadded to the dividend as may be necessary. sion is performed as in whole numbers, continuing the process to any desired extent, or till a remainder is found equal to 0. A number of decimal places, equal to the number of decimal places in which the dividend arounds the dividend to exceeds the divisor, is then marked off the right hand of the quotient. If there are not enough in the of the quotient. quotient, 0's are prefixed till the requisite number is obtained: the result is the quotient. When the numbers are expressed in any of the varying commercial scales, as pounds, shillings, and pence, two cases may arise; first, when the dividend is expressed in the varying scale, and the divisor in the scale of tens; and second when the dividend and divisor are expressed in varying scales. When the divisor is expressed in the scale of tens, the quotient is in the same scale as the dividend. The following is the rule adopted — Divide the number of units of the highest order in the dividend by the divisor; the quotient will be the number of units of the same order in the quotient sought, Multiply the remainder by the number of units of the next lower order which make one of this order, and to the product add the number of units of the next lower the product add the number of thinks of the next lower order in the given number; divide this sum by the divisor, and the quotient will be the number of units of this orderin the quotient sought. This operation is continued till the lowest order of the scale is reached, and the result is the quotient sought. Thus, let it be required to divide £25. Ss.6d. by 3, the operation is as follows :-

The operation may, however, be much simplified in practice. When both dividend and divisor are expressed in varying scales, it is necessary that both should be reduced to the same unit, and the quotient is consequently expressed in the scale of tens. As an instance, divide £25. 10a. 9d. by 18s. 11d. If both are reduced to pence, they stand £25. 10a. 9d. = 6,120d.; and 18s. 11d. = 227d.; whence,

$$\frac{6129}{227}$$
 = 27, the quotient required.

number of times the divisor is contained in the result forms the second figure of the quotient. The operation is continued till all the figures of the dividend. The operation is continued till all the figures of the dividend are seed; the final result is the quotient sought. If the final remainder is 0, the division is said to be exact, or the dividend contains the divisor an exact number of the dividend and dividend division is also performed in varying scales, either in terms, ordinary fractional units, or in the varying scales of commerce. If the numbers to the divisor. The result is the quotient sought. If the signs of the divisor are alike, the sign be divided are fractions, dividend and divisor are conditions. In vulgar fractions, dividend and divisor are conditions of algebraical division includes

### Division

Divisor

the division of a polynomial by a monomial. In this case each term of the polynomial is divided separately by the divisor. The algebraic sum of the separate results is the quotient. The third division is the division of polynomials. Both dividend and divisor are arranged with reference to the same leading letter. The first term on the left of the dividend is then divided by the first term on the left of the divisor, and the quotient forms the first term of the quotient. The divisor is then multiplied by the term of the quotient found, and the product subtracted from the dividend for the first remainder. The first remainder is then divided by the first term of the divisor for the second term of the quotient. The divisor is multiplied by this term of the quotient, and the product subtracted from the first remainder to make the second remainder. The operaremainder to make the second remainder. The opera-tion is continued till a remainder is found whose first term is not exactly divisible by the first term of the divisor. The operation of the division of polynomials may sometimes be shortened by various methods. Among these may be mentioned synthetic division, which is applicable when the dividend and divisor are homogeneous, and contain only two letters. In the division of radicals, the process depends upon reducing the radicals to equivalent ones of the same degree. A number may also be divided by another by subtracting the logarithm of the divisor from the logarithm of the dividend: the number corresponding to the remainder in the logarithmic table is the quotient required.

Division, in Log., is the separating a thing into several parts or ideas. Logicians distinguish three kinds of division:—1. When the genus or kind is divided by its species or differences; 2. when a thing is divided into several classes by opposite accidents; and 3. when the accidents themselves are divided according to the subjects in which they inhere. The laws of division are,—1. That it be full and adequate,—that is, that the members of it entirely exhaust the whole thing divided; 2. that the members of the division be opposite; 3. that one member of the division be not contained in the other, so that the other may be affirmed of it; 4. the division should not be into too many or too general parts; and 5. the members, unless the subject require it, should not be too

unequal.

DIVISION OF LABOUR, in Pol. Ec., is applied to that necessary division of occupations which is a consequence of man's living in society. In that rude state of society m which there is no division of labour, every man endeavours to supply by his own industry his wants as they occur. "When he is hungry, he goes to the forest to hunt; when his coat is worn out, he clothes himself with the skin of the first large animal he kills; and when his hut begins to go to ruin, he repairs it as well as he can with the trees and the turf that are nearest to it." But as men came to live in society, they found But as men came to live in society, they found that one person could produce more by confining his attention to only a few objects than by carrying on a great many. Their wants, too, gradually increased; and as the means of supplying these could only be obtained through labour, they were naturally led to seek the greatest amount of production from the least seek the greatest amount of production from the least expenditure of labour. Hence the principle of division of labour is the very foundation of any social system, and must have existed from very early times; but it remained for political economy to discover its nature, uses, and results. Adam Smith was the first to point out definitely the great importance of this principle. "The greatest improvement," he says, "in the productive powers of labour, and the greater part of the skill, dexterity, and judgment with which it is anywhere directed or applied, seem to have been the effects of skill, dexterity, and judgment with which it is anywhere directed or applied, seem to have been the effects of the division of labour." He instances the trade of a pin-maker, in which, he says, "one man draws out the wire, another straights it, a third cuts it, a forth points it, a fifth grinds it at the top for receiving the head. To make the head requires two or three distinct operations; to put it on is a peculiar business; to whiten the pins is another; it is even a trade by itself to put them into the paper; and the important business of making a pin is in this manner divided into about eighteen distinct operations." In a small mannfactory, he says, whore only ten persons were engaged. factory, he says, whore only ten persons were engaged, they could make upwards of \$6,000 pins a day, or \$,800 each. Such has been the progress of improve-

ment since his day, that each person can now produce more than double that number. The great increase of the quantity of work produced in consequence of the division of labour is owing, he says, "to three different circumstances: first, to the increase of dexterity in every particular workman; secondly to the saving of the time which is commonly lost in passing from one species of work to another; and lastly, to the invention of a great number of machines, which facilitate and abridge labour, and enable one man to do the work of of a great number of machines, which facilitate and abridge labour, and enable one man to do the work of many." As it is the power of exchanging that leads to the division of labour, so the amount of labour, and consequently the extent of division, must always be limited by the extent of the market. If there were no means of exchanging, men would be obliged to provide everything that they require for themselves. Hence it is, that in populous cities trades are subdivided to a nuch greater extent then in villages or country parts. much greater extent than in villages or country parts; and hence, too, the advantages to be derived from the division of labour can only be reaped in their full extent where there is a great power of exchanging or an extensive market. Another important consequence of the division of labour, and one which Adam Smith, though he has alluded to it, has not prominently stated, is the power possessed by every country of availing itself to a certain extent of its natural or acquired advantages, which is called the territorial division of labour. Nature seems to have intended to unite, by mutual dependence, all the countries of the world into mutual dependence, all the countries of the world into one commercial family. For this purpose, different districts or countries have different products and capacities; so that some are more particularly adapted for carrying on some branches of labour, and others for others; and the full advantages of which can only be reaped by free intercourse between the different nations. The commerce of one country with another The commerce of one country with another nations. is merely an extension of that division of labour by which so many benefits are conferred on the human race. By means of nutual intercourse, mankind are enabled to distribute their labour as best fits the genius of each particular country and people; and the indus-try of the whole is thus rendered incomparably more productive. There is unother feature of this question which it is necessary to glauce at, and that is, the effect of this minute subdivision of labour upon the workmen themselves. Some hold that it reduces men to the character of mere organized machines, and affords them no scope for mental development. This, however, we do not believe to be the case. Man's mental condition is principally dependent upon the circumstances by which he is surrounded and the persons with whom he associates. Rarely does his occupation, especially if it be of a manual kind, exert great influence upon it. In rural districts, where employ-ments are less divided than in large cities, we do not find that the people in the former case display more intelligence than the latter, but the reverse; the frequent intercourse among their fellows, and the great variety of objects that are constantly exciting the attention of the city man, giving him a greatly superior mental training to the other. But we believe a division of labour to be good for man, because it is inseparably connected with civilization; for, if the one is beneficial, so of necessity must be the other.

DIVISION OF TIME.—The length of sounds in Mus. is regulated by dividing the time occupied in the performance of any given melody or harmony into regular formance of any given melody or harmony into regular portions called measures. In order to illustrate this more clearly, we will take a straight line and divide it into equal portions,—the straight line to represent the time of the melody, and each division to constitute a measure or bar. The time must be kept equal by motions of the hand or foot. Presuming the true time of a crotebet to be known, we will suppose the bar to be subdivided into four crotehets (as in common time), when the half of the measure will of course be two crotehets; therefore the hand or foot being raised, we crotchets; therefore, the hand or foot being raised, we put it down for the first note, raise it with the third, and lower it again to commence the next bar. Time is to music what rhythm is to poetry, and cannot be too widdle observed.

to music was rayellar and rigidly observed.
Divison, dic-1-zor, one of the factors of the dividend,—the factor by which the dividend is divided.
Divisors of a number are those numbers by which it is exactly divisible. Thus, 1, 2, 3, 4, 6, and 12 are

### Divi-divi

divisors of 12, because 12 hay be divided by each of them without a remainder.

them without a remainder.

Divi-divi. (See Clearings.)

Divonce, di-core (Lat. dicordium, from diverto, I turn away or separate), denotes a separation by law of husband and wife; and is either a divorce a vinesto matriagen; (from the bond of marriage), or a messe of there (from bed and beard), the marriage in the former case being dissolved, but not so in the latter, the par case being dissolved, but not so in the latter, the par-ties being only debarred from living together. Accord-ing to the law of Moses, "when a man hath taken a wife and married her, and it come to pass that she find no favour in his eyes because he hath found some un-cleanness in her; then let him write her a bill of divorce-ment, and give it in her hand, and send her out of his house."—(Dieut, xxiv. 1.) After ninety days the wife might marry again; but after she had contracted a second marriage, though she should be again divorced. second marriage, though she should be again divorced second marrage, mought not take her again to be his wife. The like lax notions on the subject of marriage appear to have prevailed generally in the East at that early period; and even at the present day, as among the Arabs, a lustband can divorce his wife on the slightest occasion; Burckhardt mentioning that he had seen Arabs, not more than forty-five years of age, who were known to have had more than fifty wives. The Mahommount to nave not more than may nives. The Manon-medan law allows of a separation by mutual consent, giving the wife the right of retaining her marriage por-tion unless she agrees to relinquish a part of it as the price of the separation. They are permitted to sepa-rate and reunite twice; but, after the third divorce, he cannot again receive her until she has been married and directed by another. Among the Histograph and divorced by another. Among the Hindoos and Chinese, the notions are still more lax on this subject, and a husband may divorce his wife upon the slightest grounds, or even without assigning any reason. Among the causes that are considered to justify separation are loquaciousness or quarrelsomeness on the part of the wife. The laws of the several Grecian states regarding divorce differed greatly from each other: in some it was permitted on slight grounds; in others the laws were stringent regarding it. At Athens divorce was permitted on slight causes, but not without giving a bill containing the reasons for it, to be approved, if objected to, by the chief archon. At Sparts, divorces seem to have been very rare. By the early laws of Rome, the husband was not allowed to divorce his wife without just cause; as for adultery, drunkennness, counterfeiting his keys, or poisoning his children. Other causes were afterwards added, and at length divorces took place on very frivolous pretexts, and the women enjoyed the same liberty as the men. Hence Augustus introduced a law enacting additional ceremonies in obtaining a divorce, and requiring the presence of seven witnesses, before whom the marriage contract should be torn. By the Theodosian code, among the causes for which a busband could divorce his wife, were, adultery; the being a witch or a murderess; commit-ting sacrilege; violating sepulchres, or buying or sell-ing one free-born to slavery; favouring thieves and robbers; frequenting sights or theatres, or feeding with strangers against the wishes of her husband; the being privy with those that plot against the state, or dealing falsely or offering blows. If the wife could prove the husband guilty of any of these crimes, she prove one nususand gainty of any of these extines, and also was at liberty to leave him; but could not marry again until after the expiry of one year, whereas the lusband might marry again immediately. Voluntary divorces were abolished by one of the novels of Jastinian, but were afterwards revived by another smoot under the emperor Justin, and the practice; and may also order him to pay the costs amounted to have continued in the Eastern empire down to the 9th or 10th century, when it was flually sundaid by the influence of Christianity. The Scripture doctrine on this subject is enunciated by our flavour, when he says, "Have ye notreed that he who less the provision for the maintenance them at the beginning made them make and female; and said, for this cause shall a man leave father and mother, and shall cleave to his wife, and they twain shall be one flesh." "What, therefore, God hath joined togother, let not man put assuder." "Moses, because of the hardness of your hearts, suffered you to put away your wives; but from the beginning it was not so; and I say usto you, Whosever shall put away his wife exceptit He for fornication, and lso was at liberty to leave him; but could not marry

## Divorce

shall marry another, committeth adultery; and whose marrieth her who is put away doth commit adultery."
—(Matt. xiz. 4—9.) Our Saviour's declaration naturally
became the foundation of the law of divorce in all Christian countries; and after marriage was raised to the dignity of a sacrament by Pope Innocent III., in 1215, the ecclesiastical courts claimed the sole jurisdiction over it. The papel canon law regarded the bond of marriage as indissoluble, but allowed a divorce a measa et thore for five causes; viz., adultery, impotency, cruelty, infidelity, and ingressus religionis. The Church, however, assumed to itself a power to grant dispensations for absolute divorces. The principle of the canon law, not admitting of an absolute dissolution of the marriage contract for any cause whatever, governed the ecclesi-satical law of this country. A divorce was only a judicial separation a mensa et there, not sllowing either of the parties to marry again during the lifetime of the other. An individual, however, if able to incur the expense, might, after a sentence of divorce a mensa et thore, pronounced by the ecclesiastical court, by obtaining an act of parliament, procure a suspension of the law, and, by legislative interference, obtain a directivity of his marries. dissolution of his marriage. There were certain causes, however, which were regarded as nullifying marriage and justifying a divorce a vinculo matrimonii; as, vious marriage still subsisting, or affinity within the prescribed degree,—the sentence in such a case being declaratory only that the marriage was originally null and void. The law of England granted judicial separation only on the grounds of adultery or cruelty; and the effect of it was to place the woman in the same position as a femme sole, enabling her to hold and deal with property free from the control of her husband; and in the case of the man, relieving him from all obligation to support his wife. By act 20 & 21 Vict. c. 85, an entire change was effected in the law of divorce in England. and a court instituted with exclusive jurisdiction in matters matrimonial, and with authority, in certain cases, to decree the dissolution of a marriage. The entire jurisdiction, therefore, previously exercised by the ecclesiastical courts in matters of divorce, was transferred to this court under the name of the Court for Divorce and Matrimonial Causes (see next article); and sentence of judicial separation (having the same effect as a divorce a mensa of thoro) may be obtained effect as a divorce a mense of thorough may be obtained, either by the husband or wife on the ground of adultery, or cruelty, or desertion without cause for two years and upwards. This court has also the power of dissolving a marriage on a petition preserved by the husband, setting forth that his wife bad been guilty of adultery, or on a petition by a wife on the ground that her hus-band had been guilty of incestuous adultery, or of adultery with cruelty, or adultery with desertion for two years or upwards. It is the duty of the court not to satisfy itself as to the facts alleged, but also whether or not the petitioner has been in any manner accessory to or conniving at the adultery, or has con-doned the same; and shall also inquire into any counter charge which may be made against the petitioner. any of these cases, or if there is reason to believe that the petition is presented or prosecuted in colinsion with either of the respondents, then the court shall dismiss the said petition. The court may also, if it sees fit, order the bushand to secure to the wife such gross or order the husband to secure to the wite such gross or annual sum of money for any term not exceeding her own life, as it may deem reasonable in the circum-stances. It can also allow damages, if asked for, against the adulterer, and may siso order him to pay the costs of the proceedings. It has also the power to declare in what manner such damages are to be paid or ap-plied, and to direct that the whole, or any part thereof, shall be settled for the benefit of the children, if any,

the children of the marriage, or either of them. Either party may appeal from a decision of the judge ordinary to the full court, and either party dissatisfied with the to the full court, and either party dissatisfied with the decision of the full court on any petition for the dissolution of a marriage may, within three months after the pronouncing thereof, appeal therefrom to the House of Lords, it then sitting, or within fourteen days after its next meeting. Every decree for a divorce is thus a decree nist, and not absolute till after the expiration of not less than three months, within which time it shall be lawful for any person to show cause why such decree should not be made final. After the decree has become final, it shall be lawful for the respective parties thereto overthe again as if the prior marriage had been disto marry again, as if the prior marriage had been dis-solved by death; but it is provided that "no clergyman in holy orders of the united church of England and Ireland shall be compelled to solemnize the marriage of any person whose former marriage may have been dis-solved on the ground of his or her adultary, or shall be liable to any suit, pounlty, or censure, for solemnizing, or refusing to solemnize, the marriage of any such per-The law of Scotland on this subject differs materially from that of England. According to the former, if the husband should either abandon his family, or turn his wife out of doors, or by barbarous treatment endanger her life, or render her condition quite uncomfortable, the judge will, on proper proof, authorize a separation a mensa et thoro, and award a separate alimony to her, suitable to her husband's fortune, to take place from the time of the separation, and to continue till there shall be either a reconciliation between the parties or a sentence of divorce. Actions of dithe parties or a sentence of divorce. Actions of di-vorce were formerly brought before the Supreme Commissary court of Edinburgh; but by act of parliament in 1830, they were removed to the jurisdiction of the court of Session; and questions of fact connected with such cases may, at the discretion of the court, be tried by jury. The grounds of divorce are two: adultery, and wilful desertion, the latter of which must have continued for four years. The pursuer must also swear that the action is not carried on by collusion. The offcuding parties cannot intermarry. The effect of a decree of divorce is, that the offending party forfeits all benefit which might accrue to him or her from the marriage. In France, before the revolution of 1782, marriage was, in accordance with the principles of the canon law, held to be indissoluble; but after that event very lax notions prevailed on this subject, and divorces were permitted on very slight grounds. The Code Napoléon greatly restricted this liberty, but allowed a divorce to either party on the ground of adultery, outrageous ill-usage, and some other causes. In Holland, divorce a vinculo matrimonii is obtainable on the ground of adultery or desertion. In the different states of America the laws are by no means uniform on states of America the isws are by no means uniform on this subject. In several of them no divorce is granted but by special act of the legislature; but generally, divorce a vincula may be granted by courts of justice for adultery. In most of the states, in addition to adultery, intolerable ill-usage or wiful desertion (in some for seven, in others for three years), will form grounds for a divorce a ninculo matrimonii.

DIVORCE AND MATRIMONIAL COURT is a court instituted by act 20 & 21 Vict. c. 85, for trying matrimonial causes, and granting decrees of divorce, which had been formerly under the jurisdiction of the ecclesissical courts. The judges of this court are, the lord charellor, the lord charellor, the lord cherjustice of the court of Queen's Bench, the lord chief justice of the court of Common Pleas, the lord chief baron of the court of Exchequer, the senior puisne judge for the time of the three lastmentioned courts, and the judge of her Majesty's court of Probate, the last of whom to be the judge ordinary. By 23 & 24 Vict. c. 144, the powers of the judge ordinary were much extended, so that he may now alone pronounce a decree of divorce, a power which was at first reposed in the whole court. DIVORCE.)

DIVORCE.)

Do, do, the name of the first note of the natural major diatonic scale. It has been long since substituted for that of ut, which was employed by Guido, the latter monosylbable being rejected as too hard and rough.

DOURTH, do-se'-ts (Gr. dokein, to seem), an heratical sect that aprung up very shortly after the foundation of the Christian religion. As their name implies, they

disbelieved in the incarnation of Christ; asserting that he acted and suffered in appearance only. It is believed by some divines that several portions of St. John's Gospel were especially directed against the doctrines held by the Docetae.

Docu, doc (Tent. docke, probably from dekken, to inclose), an inclosed space or artificial basin in the bank of a river or side of a harbour, contrived for the reception of ships. There are two kinds of docks,—wet and dry docks. A wet dock may either have gates to retain the water in it, so that ships may remain in it afloat, or be left open for the tide to flow in and out. A wet dock without gates is generally called a basin, the term is, however, sometimes applied to a wet dock the term is, however, sometimes applied to a wet dock with or without gates. A dry dock either becomes dry by the ebbing of the tide when the gates are left open, or by shutting the gates at low water and pumping out whatever water may be left at that time. Docks of this kind are employed for repairing and examining ships. Wet docks are used for the loading and unloading of vessels, and contrived generally for the purpose of keeping them always aflost. The first wet dock made for commercial purposes in this kingdom was formed in 1708, at Liverpool. At nearly all the most important ports and harbours in Britain now there are several extensive and commodious wet docks. Wet docks are usually surrounded by quay now there are several extensive and commodious wet docks. Wet docks are usually surrounded by quay or wharf walls of solid masonry or brick-work, and are entered by means of a lock, having two gates, usually in two folding leaves each: this arrangement, in many places, enables vessels to enter or go out a considerable time before or after high water. Dock gates, till late years, were opened and shut by means of chains worked by hand, either by capstans or winders; hydraulic machinery is, however, now much used. The principal docks in the world are those of London, Liverpool, and Birkenhead. In London, the Commercial dock, situated at Rotherhithe, has an area of mearly 50 acres, four-fifths of which are water: it is principally used in the corn and timber trade. The West-India docks extend across the Isle of Dogs, and consist of two portions,—the im-Isle of Dogs, and consist of two portions,—the import dock and the export dock; they are both 680 yards in length, and between 130 and 170 yards in width. The East-India docks are situated at Blackwall, below the entrance to the West-India docks; the area of extent is 30 acres, and they are divided into the loading and unloading docks. The London docks, at Wapping, were finished in 1805; they cover a space of 28 acres, and have extensive warehouses for wine and tobacco. St. Katherine's docks, situated between the London docks and the Tower, were finished in 1828; their area is 24 acres, and they are divided into two portions, capable of receiving vessels of 800 tons burportions, capable of receiving vessels of own consultations, capable of receiving vessels of own each cheer state dense only 11 acres of the space are water, the rest being taken up with large warehouses and extensive quays. The Victoria docks are situated on the Plainet own marshes, on the north side of the Thames, inmediately below the East and West India docks; they comprise a half-tide basin of 16 acres, an inner dock of 74 acres, and a portion (12 acres) of the canal intended to intersect the eastern lands of the company. Some very large warehouses are attached to these docks, used chiefly for the storing of tobacco. In the following table will be found a nearly correct statement of the number and areas of the docks in Great Britain, including those locks or entrance-basins provided with gates, at a number of the principal ports :-

For further information concerning the docks of Great Britain see McCalloch's "Commercial Dictionary." Docks are generally the property of large companies and as their management is costly, they require to be supported by those vessels using them; this is done by levying rates, powers being granted by the acts of parliament authorizing the construction of the various docks. Sometimes dock dues are levied on vessels in bulk according to tonnage, and sometimes according to the nature or value of the goods.—Ref. Chambers' Encyclopædia.

DOCK, the common name for some species of Rumex

(which see).

Doek, the inclosed space, usually surrounded with an iron railing or checause de friee, in which a prisoner

is placed during his trial.

DOCK WARRANTS, orders for the removal of goods stored or warehoused in the several docks. The orders are granted by the proper persons appointed at docks in favour of any one for whom the importer applies The rules laid down by the various dock companies closely resemble each other, and are very strictly attended to. Unless the rules are compiled with goods will not be delivered up. Warrants can be obtained for a whole or part of a cargo; and a warrant can also be divided into smaller warrants, and these may be assigned; a warrant may also be assigned by a holder. If a warrant is lost, a fresh warrant is not granted till the first warrant is advertised; and before it is granted the holder is obliged to enter into an agreement with the company to indemnify them in case of any future

1068. DOCKET, DOCQUET, or DOQUET, dok'-et (Welsh lociaw), is a brief summary, or abridged entry of any document or instrument on a small piece of paper or parchment. It is chiefly used in law; decrees in chancery, and other legal instruments, being thus docketed for purposes of reference. Attestations or declarations annexed to written instruments are also called dockets, especially such as are done by a notary. A docket is

also a ticket or direction tied to goods.

DOCKYARDS, yards or magazines situated near large harbours, for the purpose of containing all kinds of naval stores, timber, &c., together with all the materials requisite for the building and repairing of ships. Before the reign of Henry VIII, there were neither arsenals nor dockyards belonging to the crown; but to that monarch belongs the credit of having first founded a regular navy, by the establishment of dock-yards, and the formation of a board consisting of certain commissioners. The first dockyard erected in his reign was that of Woolwich. Those of Portsmouth, Deptford, Chatham, and Sheerness followed. Plymouth, and afterwards Pembroke, are more recently formed dockyards. All of these establishments have slips in which new ships are built, sheds and dry docks for repairing vessels, and all the requisites for rigging and fitting them out for sea. Bost-building and mastmaking are also carried on; and in some cases blocks, ropes, and sails are made and anchors forged. A brief description of several of the royal dockyards may give a general idea of their usefulness. Portsmouth dock-yard is considered the great naval arsenal of England, and the head-quarters of the British navy. It is by far the largest of the royal dockyards; and its central station with regard to the opposite coast of France, its safe and extensive harbour, and splendid anchor age at Spithead, all combine to give it prominence. The wharf-wall of the dockyard on the western side of the harbour is 3,900 feet in length; the mean depth may be 2,000 feet, and it incloses an area of more than 100 acres. Within the yard are several large basins with dry docks, double docks for frigates, building slips, &c., attached to them. On the north-east side is a row of storehouses, 500 feet in length; and the south-west side the rigging-house and sail-loft, 400 feet long. There are two hemp-houses and two sea-storehouses, extending 800 feet; while the rope-house, tarring-house, and other buildings connected with the ropery, are on the same large scale. Besides with the ropery, are on the same arge scate. Desides these, there are saw-mills, a gigantic smithery, an iron-mill, a copper-mill, a copper-refinery, in which all the old copper taken from saips; bottoms is melted are relied; and all the bolts, gudgeons, and other articles of copper used in the navy, are cast there. Connected 676

with the dockyard is a naval college, established in 1729, and a naval architectural school, the professor of which has the charge and keeps the rate of all the chronometers belonging to the navy which may not be in use. Woolwich dockyard presents a frontage of in use. Woolwich dockyard presents a froutage of 3,680 feet to the river, to which may be added 180 feet more timber-grove. The breadth is very irregular, but is estimated at between 250 and 900 feet. It has two docks with entrance from the river, and one dock with an entrance from a large basin. There are also with an entrance from a large basin. There are also a three large and two smaller building-slips, besides a boat-pond. Woolwich dockyard is more looked upon as a building-yard than as a store; but it is very com-plete in all the usual appendages of artificers workshops, storehouses, offices, &c. One of the four divisions of marines are stationed at Woolwich, where their barracks are situated. Deptford dockyard had a front wall facing the Thames, about 1 200 fact is least, and had with an entrance from a large basin. are aroused. Deputity docayar, and a rone wan facing the Thames, about 1,700 feet in length, and had an area of about 30 acres. It had three large slips, two smaller ones, and three dry docks. Its principal use was in repairing vessels. Through its proximity to London, however, it became the general magazine of stores and necessaries for the fleet. The principal stores consisted of small cordage, canvas, and ships sails, beds, hair for beds, hummocks, slops and marine clothing; anchors under the weight of about seventyfive hundred, -all above that size being made in the queen's dockyards. In 1870 this dockyard was closed and sold by the Government. It is now being converted into a water-side cattle-market. Plymouth possesses one of the finest harbours in the world, able possesses one of the intest narrows in the word, above to contain in perfect safety at their moorings more than a hundred sail of the line. The dockyard, however, has only one basin; but it is not only a good building and repairing yard, but a good refitting yard. All the dockyards are under the control of the Admiratty; and each is governed by a set of officers, who are responsible to that department. In several dockyards there are arrangements connected with the storing of guns and ammunition. In the estimates for

storing of guins and ammunition. In the estimates for 1869-70 the total cost for dockyards was £1,086,001; in 1870-71, £378,352.

DOCKYARD BATTALIONS.—In the year 1847 the workmen of the various dockyards were enrolled into a corps for the defence of the yards, and a certain number of them were trained to the use of the large guns; so that each of the battalions has artillery atguns; so that each of the battahous has artillery attached to it. Each corps is formed of clerks, artisans, and labourers. The colonel is a naval officer, and commissions are given to the others. This valuable body of men is regularly drilled, the men receiving remuneration for time lost in drilling. Sergeauts and corporals of marines usually superintend the drilling. The uniform consists of blue frock-coats and trowsers, uniform consists of blue froct-coats and trowsers, and a helmet. At first the enlistment in the deckyard battalions was voluntary, but now it is compulsory. The service, however, is very popular, and the list is well filled. When first enrolled, in 1847, the battalions numbered 9,000 men; and an item appeared in the estimates of £20,000 for their training and exercise.

Docros, dok-ter (Lat. doctor, from doceo, I teach), properly signifies a teacher or instructor, one so skilled in his particular art or science as to be able to communicate it to others. It is generally believed to have been first adopted as a distinctive title in the 12th century, and to have originated with the university of Bologue. The university of Paris followed immediately after, and, in 1145, conferred the degree of doctor in divinity on Peter Lombard. In England the degree of doctor was not introduced into the universities till the reign of John or Henry III. In modern times the title of doctor forms generally the highest degree in the faculties of theology, law, and medicine. In Germany, the title of doctor in philosophy has been substituted for the older title of master, which is still retained in this country. The universities of Oxford and Cambridge also confer the degree of doctor in music. As to the conditions and qualifications necessary to obtain this degree, see the accounts of the different universities in other parts of this work.

Doctor IN MURIC, a musician upon whom the demunicate it to others. It is generally believed to have

Dorron universities in other parts of this work.

Dorron in Murat, a musician upon whom the degree of doctor has been conferred by some university.

The name of the first professor to whom this title was granted not being clearly known, the date of its origin in England cannot be clearly demonstrated. According

### Doctors' Commons

to Anthony Wood, it was first instituted in the reign to Anthony Wood, it was first instituted in the reign of Henry II.; while Spelman fixes its foundation in that of John. By the qualifications formerly required of a candidate for either a doctor's or a bachelor's degree, it is clearly shown that music was considered a purely speculative science. No importance was attributed to skill in composition; the ability of reading and expounding Boethius was received as a much the contributed to the the first that the same first that the first that the same first that the first. higher criterion of scientific acquisition than the finest specimen of inventive harmony and melody. By the more modern statutes, however, higher qualifications are rendered necessary; the candidate being required by them to submit for the inspection of the musical professor a composition in eight vocal parts, with instrumental accompaniments.

Doctoss Common. or Collegs of Civilians, is a college, or "common-house," founded by Dr. Harvey, dean of the Arches, about the beginning of the reign of Queen Riuzbeth, for the professors of civil law in London, and is situated near St. Paul's Churchyard. The original building was burned down in the great fire of 1666; but it was afterwards rebuilt in 1672. Besides being the residence of the doctors of the civil law, who all used to live here, as to diet and ledging, in a collegiate manner, "commoning together," it was also the official residence of the judges of the court of Arches of Canterbury, of the Admiralty, and of the Prerogative court, who held their courts here. The only courts that still continue to exercise their The only courts that still continue to exercise their functions here are the court of Arches, the court of Admiralty, the Archdeacon's court, and the court of Faculty. In 1768 the members of this society obtained a royal charter, and were incorporated under the name of "the College of Doctors of Law exercent in the Ecclesiastical and Admiralty courts." The college of the court of the president of the days of the Arches for the Ecclesiastical and Admiralty courts." The college consists of a president (the dean of the Arches for the time being), and of those doctors of law who, having regularly taken that degree in either of the universities of Oxford or Cambridge, and having been admitted advocates, in pursuance of the rescript of the arch-bishop of Canterbury, shall have been elected fellows of the college in the manner prescribed by the charter. Hence no one can be admitted a member, or allowed to practise as an advocate in the courts at Doctors' Commons, who has not first taken the degree of doctor of laws in one of the English universities. Proctors in these courts discharge duties similar to those of solicitors and attorneys in other courts. In order to be admitted a proctor to practise in the court of Arches, it is necessary to have served a clerkship of seven years under articles with one of the senior proctors, who must be of five years' standing, and who is prohibited from taking a second clerk until the first shall have accorded for shall have served five years. The proctors appear in court in black stuff gowns, the advocates wearing wigs, bands, and black silk gowns, exchanged on certain days for scarlet cloth gowns, which, in the case of graduates of Oxford, are bound round with taffeta,—of Cambridge, trimmed with white minever.

Doctrinaire, dok-trin-aire' (fr.), denotes properly a man who is the supporter of a particular doctrine, or who is a man of doctrines. In general, it is used in a had sense, as applied to those who hold pedantic or un-practical views. In this sense it was applied in France, during the Restoration, by the reactionary court party, to a faction of the parliamentary opposition, who wished to carry out rational and scientific doctrines in politics against all arbitrary measures. This party went out from the salons of the due de Broglie, and had, as its leader in the chamber, Royer Collard, being supported in the press and before the public by Guizot. Their watchword was a constitution on the basis of the charter of Louis XVIII. After the revolution of 1830, Guizot, Brogie, and others of this party, became ministers and supporters of the government, and their principles came to be very much the same as those of the then

## Dodo

influence the heart and life. "Thus, the idea of God's sovereignty excites submission; his power and justice promote fear; his holiness, humility and purity; his goodness, a ground of hope; his love excites joy; the obscurity of his providence requires patience; his faithfulness, confidence, &c."

DOGUMENT, dokument (Tat document)

faithfulness, confidence, &c."

Document, dok'-u-ment (Lat. documentum, from doce, I teach, as teaching or showing something), in Law, is applied to any written muniment produced in proof of any feet sesewited.

Dodecacon, do-dek'-d-gon (Gr. dodeka, twelve; gonia, an angle), in Geom., a polygon which has twelve angles and twelve sides. When the angles and the sides are each of them equal, the dodecagon is a regular one and may then he insertibed in or incumercially sides are each of them equal, the dodecagon is a regular one, and may then be inscribed in or circumscribed by the circle, the sum of its interior angles equalling twenty right angles. If the side of a dodecagon be 1, its area will=3×(2+√3), or 11·196 nearly.—In Fort., the term is applied to a place surrounded by twelve bastions. (See REGULAR FIGURE.)

DODRAHIDBON, do-de-kui-he'-dron (Gr. dodeka, twelve; edra, a base), in Geom., one of the five regular solids of Plato, being contained under a surface com-posed of twelve equal and regular polygons or bases. (See REGULAR BODY.)

Dono, do'-do, a gau, of birds said to be now extinct, but of whose existence within the last three centuries there is abundant evidence. When, in 1598, turies there is additional evidence. When, in Addition the island of Mauritius was discovered, the bird in question was so plentiful that the sailors ate the flesh to satiety, as it was easily killed, and its flesh, especially the breast, much relished. It is described as being considerably larger than a swan, weighing sometimes fifty pounds, with a very bulky and heavy form. The bill was long and strong, depressed at the base, with a separate and much arched spical portion, which was so sharp and strongly hooked at the tip that the dodo has been considered by some naturalists as

approaching the predacious birds. The nostrils were placed on the sides of the depressed portion of the bill, which was covered by a naked skin; the face was similarly clothed. The feet, which were very short and stout, bore a considerable resemblance to those of the pigeon. The wings were also very short, and quite incapable of raising the bird in the air, even had they been furnished with the ordinary stiff quil-lifeathers; but, in place of these, they bore a few soft decomposed plumes like those of the ostrich and the teal, and were adorned with a tut of similar but smaller feathers. approaching the predscious birds. The nostrils were piumes like those of the ostrich and the teal, and were adorned with a tuft of similar but smaller feathers. This rudimentary condition of the wings led to the dodo's, being placed among the cursorial birds by many writers. The general colour of the dodo was a blackish grey, but the plumes of the wings were of a light ash-colour. In Tradescant's catalogue ("Museum Religible ash-colour of Religible ash-colour as Calletting Religible research light ash-colour. In Tradescant's catalogue ("Mussum Doctrina, doh'-trin (Lat. doctrina, from doceo, I Tradescantisnam; or a Collection of Rarticise preserved at South Lambeth," by John Tradescant; London, cither as a matter of faith or practice; and hence the 1856), we find, among the "whole birds, doda, from the team has come to be applied to a variety of opinion; that have been adopted and inculcated in religion, philosophy, &c. The doctrines of the Bible are the first brate that this was a dodo there can be no doubt; for we have the testimony of an eye-witness whose ornithological competency cannot be doubted, in the affirmation of religion, and ought to logical competency cannot be doubted, in the affirmation.

dodo, and immediately beneath his translation of Bontius, has the following words:—"We have seen Bontins, has the following words:—"We have seen this bird dried, or its skin stuffed, in Tradescant's cabinet." Le Strange, in his observations on Sir Thomas Browne's "Vulgar Errors," speaks of a dodo exhibited (probably in a caravan) in the streets of Loudon:—"About 1638, as I walked Loudon streets, I am the picture of a street for leave out the streets. I saw the picture of a strange fowl hong out upon a cloth, and went in to see it. It was kept in a chamber, and was a great fowle, somewhat bigger than the lurgest turkey-cock, and so legged and footed, but stouter and thicker, and of a more erect shape; coloured before like the breast of a young cock tesan (pheasant), and on the backe of dunn or deare colour. The keeper called it a dodo, and in the ends of a chimney in the chamber there lay an heap of large pebble-stones, whereof he gave it many in our sight, some as bigg as nutmegs; and the keeper told us shee eats them, con-ducing to digestion; and though I remember not how farre the keeper was questioned therein, yet I am confident that afterwards she cast them all agayne." Tradescant's stuffed specimen passed to the Ashmolean Tradescant's studed specimen passed to the Annuciean Museum at Oxford; but, being allowed to fall to decay, it was, by order of the curators, destroyed in 1755. Luckily, however, the head and one of the feet escaped destruction, and these, together with one other foot, safely stored in the British Museum, comprise the sole known remains of a creature commonly eaten within the last three hundred years.

DOE, JOHN, jon do, in Law, was, previous to the passing of the Common Law Procedure Act (1852), a fictitious personage, who was usually employed as plain-tiff in actions of ejectment against an equally fictitious defendant, Richard Roe. The claimant John Doe served the tenant in possession of the land with a declaration the tenant in possession of the land with a decaration in ejectment against Richard Roc. Subjoined to this declaration was a notice to appear, addressed to the tenant in possession by name, in the form of a letter from Roc, informing him that he, Roc, was sued as a casual ejector only, and had no title to the pre-mises and would make no defence and therefore adas a casual ejector only, and had no title to the premises and would make no defence, and therefore advising him to appear in court and defend his own title, otherwise he, Roe, would suffer judgment to be had against him, and he would thus be turned out of possession. If the tenant in possession did not, in due time, take the proper steps to be admitted defendant in the place of Roe, then upon judgment being given against Roe, the real tenant would be turned out of possession by the sheriff.—Ref. Stephen's Commentaries on the Law of England.

on the Law of England. Dog, dog (Canis familiaris).—To use the oft-quoted words of a great naturalist, "The dog exhibits the most words of a great naturaist. "The dog extinits he most singular, the most complete, and the most useful conquest that man has made. The whole species is become our property; each individual is entirely devoted to his master, adopts his manners, distinguishes and defends his property, and remains attached to him even unto death; and all this springs not from necessity—not from restraint, but simply from gratitude and a true friendship."—(Cuvier.) In all ages the origin of the domestic dog has been a question, and one most difficult of solution, with the most learned naturalists. Some are of opinion that the breed is derived from the wolf; others maintain that it is a familiarized jackal; all agree that no trace of it is to raminarized packal; all agree that no trace of it is to be found in a primitive state of nature. Wild dogs still exist: India furnishes them. There thousands exist in a completely independent state, and without exhibiting any wish to share the dwellings of man, Close observation of these animals, however, throws little light on the subject; and after all it would appear that they are naught else than abandoned canine vaganced. bonds; and in their prowlings about the skirts of the villages they exhibit a fearlessness of human beings that, since it does not spring from ferocity or defiance,

since have resumed some of the characters of the wolf." Mr. Bell, whose opinion on the subject is of high value, says, "In order to come to any rational conclusion on says, 'In order to come or any restonant contents on this head, it will be necessary to escertain to what type the animal approaches most nearly after having for many successive generations existed in a wild state, removed from the influence of domestication and of association with mankind. Now we find that there are several distinct instances of the existence of dogs in such a state of wildness as to have lost even that common character of domestication,—variety of colour and marking. Of these, two very remarkable ones are the dhole of India and the dingo of Australia; there is, besides, a half-reclaimed race among the Indians of North America, and another, also partially tamed, in South America, which deserve attention; and it is found that these races, in different degrees, and in a greater degree as they are more wild, exhibit the lank and gaunt form, the length of limb, the long and alender muzzle, and the great comparative strength which characterize the wolf; and that the tail of the Australian dog, which may be considered as the most remote from a state of domestication, assumes the slight bushy form of that animal. We have here, then, a considerable approximation to a well-known wild animal of the same genus in races which, though doubtless descended from domestic ancestors, have

DALMATIAN DOG.

gradually assumed the wild condition; and it is worthy of especial remark that the anatomy of the wolf, and its osteology in particular, does not differ from that of the dog in general more than the different kind of dogs do from each other. The cranium is absolutely similar, and so are all, or nearly all, the other abscillety similar, and so are all, or nearly all, the other essential parts; and to strengthen still further the probability of their identity, the dog and the wolf will readily breed together, and their progeny is fertile. The obliquity of the position of the eyes in the wolf is one of the characters in which it differs from the dog; and although it is very desirable not to rest too much on the effects of habits or structure it is not perhaps effective the point structure, it is not, perhaps, straining the point to attribute the forward direction of the eyes in the dogs to the constant habit for many successive generations of looking forward to their master, and obeying rations of footing forward to their master, and oveying his voice." The latter part of this argument is, however, of too theoretic and speculative a character to carry weight, or, as some insist, to be worth weighing. With regard to the alleged untamably savage disposition of the wolf, Mr. Bell disposes of the objection by specifying two olf, when his disposes one of which is of a she-wolf that, since it does not spring from ferocity or defined, would seem to betoken a confidence in man never to be found in the roaming wolf or jackal. In certain Bastern cities, again, the canine prowlers are very numerous, and sometimes dangerous to approach, on account of their ferocity. This, however, is small proof of their wolfsh origin. As Colonel Hamilton Smith truly observer, "If domestic dogs were merely wolves modified by the influence of manie wants, surely the curr of Mahamedan states, released domestic care, and small proof of the subspace of the surely to the dog and the wolf, is the sale of their wolfsh origing them to the bars of her truly observer, "If domestic dogs were merely wolves modified by the influence of manie wants, surely the life out of the whole of her precious modified by the captesia care, and only solerated in the capacity of seawengers, would long fact that in both the period of gestation is the same, relating two anecdotes, one of which is of a she-wolf confined in the gardens of the Zoological Society in the Regent's Park. This creature, who had pups was constantly in the habit of bringing them to the bars of her den that they might be caressed by the visitors, till at length through content of first the habit.

sixty-three days. The young of both wolf and dog are born blind, and see at the same, or about the same time, namely, at the expiration of the tenth or twelfth day. A satisfactory classification of the different kinds of dog has not yet been arrived at. What some naturalists regard as types, others regard as mere mongrel races. It is hard to found a principle of arrangement; form does not afford it, neither does the character of the fur; kinds that are totally dissimilar associate as easily as those that are closely allied. One of the best arrange-ments is that made by Colonel Hamilton Smith, wherein the demestic dogs are grouped in six sections:—I. the Wolf-dogs, including the Siberian, Iceland, Esquinaux, Newfoundland, Northe, sheep, great wolf, Great St. Bernard, Pomeranian dog, &c.; 2. Watch and Cattle dogs, including the German boar-hound, Danish dog, matin, dog of the North American Indians, James and, mann, dog of the North American Indians, &c.; 3. the Greyhounds, including the Brinjaree dog, different kinds of greyhound, Irish hound, Inrcher, Egyptian street dog, &c.; 4. the Hounds, including the bloodhound, old Southern hound, staghound, foxhound, harrier, beagle, pointer, setter, spaniel, springer, cocker, Blenheim dog, water-dog, or poodle, &c.; 5. the Cur dogs, including the terrier and its allies; 6. the Mastiffs, including the different kinds of mastiffs, bull-dog, pue-dog, &c.

Instiffs, bull-dog, pug-dog, &c.
Dog-days. (See Canicular Days.)
Dog-fish (Seellinus catalus), the common name of come of the smaller species of shark. The best known is the picked dog-fish, which is found in the European seas, and attains a length of about three feet. It belongs to the family Spinacida, of which one characteristic is the presence of a spine before the two dorsal teristic is the presence of a spine before the two doesnatins. The body is long and tapering; the bend flat; the snout conical; the teeth in both jaws sharp-edged, and formed for cutting. The tail fin is longer than it is troud. The upper parts are slate-grey, the under parts yellowish white. To use its spines ellensively, the dog-flish bends itself into the form of a bow, and by a sudden motion causes them to spring usunder in an opposite direction. It sometimes appears in prodigious numbers: twenty thousand have been taken in a net at one time off the coast of Cornwall. They are said to afford the best food of any of the sharks, and are commonly brought to the markets of sea-side towns. The flesh is often dried. The liver yields oil, and the refuse parts are used as manure. It causes great au-novance to fishermen by cutting the hooks from their fishing-lines.

DOG-STAR. (See LAUNCHING.)
DOG-WATCH, in Mar., are the two reliefs which take
place between four and eight o'clock r.m., each of
which being only two hours on deck. The intention of these watches is to change the turn of the nightwatch every twenty-four hours, so that the party watching from eight till twelve in one night shall watch from midnight till four a.m. on the succeeding one.

Dog-wood Bark. (See Convus.)

Dogz, doje (Ital., from the Lat. dux, a leader), the

title of the chief magistrate in the republics of Genoa and Venice. The dogate, or office and dignity of doge, was elective; the doge of Genoa being elected for two years, and at Venice for life. The office was originated in the latter city in the year 697. When the seven years, and as venice for life. The office was originated in the latter city in the year 497. When the seven tribunes by whom state affairs had been previously administered were found unequal to their posts, the Venetians resolved to replace them by a single chief magistrate, who should hold office for life. The doge was chief of the compail flust incident. was chief of the council, first minister, and personal representative of the republic; but, though invested with almost regal authority, he was not a sovereign. He could convoke assemblies, declare war, or conclude treatics, command the armies of the state, appoint the treatics, command the armies of the state, appoint the military tribunes and the judges, collect citizens, hear appeals, decide disputes between the clergy, award ecclesiastical purishments, invest bishops, and instal them in their churches. Notwithstanding these vast powers, a perusal of the history of Venice will prove, that though the Venetians allowed four centuries to clapse before they fixed the bounds, or controlled the exercise of the power of their chief magistrate, that, after that time, the doge was merely the representative of an authority which was actually reserved to the republic. In fact, he was a state pageant, who lent the

weight of his name to the acts of the senate. He could give addience to ambassadors, but not make any answer to them as from himself on matters of import-All credentials with which the senate furnished ance. All credentials with which the senate infiniteration ministers to foreign courts, though written in his name, were not signed by him, but by a secretary of state, who sealed them with the arms of the republic. Dispatches were directed to him by ambassadors, but he country than agreet in presented of the country. could not open them, except in presence of the councillors; and, although money was struck in his name, it did not bear his stamp or arms. He could not go beyond Venice without permission of the council. His children and brothers were excluded from all the chief offices of state; and so jealously did the republic regard the chief they had themselves elected, that the doge of Venice was, politically speaking, a nonentity. He could not divest himself of his dignity at will; and He could not divest himself of his dignity at will; and at his death, three inquisitors and five correctors examined into his conduct with the most scarching rigour. The personal history of the doges is inseparably incorporated with that of the republic of Venice; and the office, after an existence of eleven hundred years, yielded, with but a slight resistance, to the power of the republic of France.—Ref. Quarterly Review, vol. 31; Edinburgh Review, vol. 46; Daru's Histoire de la République de Venice, 8 vols. 8vo, Paris.

Doggen, doggen; Oly, Ja, as mall ship or fishing.

Dogger, dog'-gar (Du.), a small ship or fishing-vessel, navigated in the German Ocean, and built after the Dutch fashion, with a narrow stern, a main-mast and mizer-mast. It is principally used for fishing on the Dogger Bauk, an extensive sand-bank in the German Ocean, between England and Germany.

DOGGEREL, dog-yer-el (Ang.-Sex.), a term applied to mean, pairry, loose, and irregular rhymes, where the jingle at the end of each line is the only thing preserved in common with verse or poetry. Shakspere, in "As you like it," gives an example of it, where Touchstone says, "I'll rhyme you so eight years together, dinners and suppers, and sleeping-hours excepted. It is the right butter man's rank to market,-

> " If a hart do lock a hind, Let him seek out Rosalind. If the cat will after kind, So, be sure, will Rosalind. Winter garments must be lined, So must slender Rosalind," &c.

DOGGET'S COAT AND BADGE, dog'-gets, a prize contended for at a rowing match upon the Thames on the lat of August every year. Thomas Dogget, an actor at the theatre in Drury Lane, desirous of commemo-rating the accession to the throne of George I. (Aug. 1, 1715), left a bequest of a waterman's coat and badge to be rowed for annually. At the present time several to be rowed for annually. At the present time several prizes are rowed for on the same day. In 1861, after Dogget's coat and badge, the second and third prizes were respectively five-eighths and three-eighths of the interest of £260. 17s. 3d., formerly £200 South-Sen stock, left in the will of Sir William Joliffe, the amounts being respectively £4. 17s. 9d. and £2. 18s. 9d. The prizes for the fourth man was £1. 11s. 6d. and for the fifth and sixth men, each £1. 1s.: the last three prizes were given by the Fishmongers' company. The company are six young waterman whose amount intereshing petitors are aix young watermen whose apprenticeships have expired within the year. The locality chosen for the race is from London Bridge to the Old Swan at Chelsea. The umpire is usually the barge-master of the Fishmongers' company, and the rowers are each placed with graphs. The placed singly in a boat provided with sculls. The match excites great local and general interest, and the skill exercised, and the speed attained by the rowers, are extraordinary.

DOGMA, dog'-ma (Gr., an opinion or notion), originally meant an opinion given out as a positive assertion, not requiring to be supported by any arguments; and hence a settled opinion, a principle, maxim, or tenet, particularly in theology or philosophy. In English, the term is frequently applied in a deprecia-English, the term is frequency appared in deprecia-tory manner to assertions advanced without proof. In a theological sense, it is applied to the doctrines of Christianity advanced not for discussion but for belief; hence dogmatic theology is that branch of divinity that systematically arranges and expounds the various doctrines of Christianity, as distinguished from scho-

lastic theology, which deals with the arguments by which the truth of these doctrines may be supported. which the truth of these doctrines may be supported. The first attempt to furnish a complete and coherent system of Christian dogmas was made by Origen in the 3rd century, in his work "De Principiis." He was followed, in the 4th century, by Augustine, with his work, "De Doctrina Christians." The first, however, to treat this subject systematically was John Damascenus, who flourished in the 8th century. In the middle ages ingenious examinations of the Christian doctrines were made by the schoolmen; but agitating, as they did, subtle questions of little practical importance, they loaded the science with useless refinements. Among the Protestant reformers, Melancthon was the first who wrote a compendium of the Christian doctrine, which is still justly esteemed. The spread of the critical philosophy of Kant gave a fresh stimulus to this branch of theology in Germany, and since that time it has been extensively cultivated in that country. The most recent important work on this subject is that of J. Peter Lange, "Philosophische Dogmatik" (Heidel, 1849-51). Several Roman Catholic theologians in Germany have recently distinguished themselves in this field, some inclining to liberal notions, and others supporting the rules of the Church. It is worthy of remark that Nitsch and Beck have, in recent times, treated Christian dogmatics and morality in doctrines were made by the schoolmen; but agitating, times, treated Christian dogmatics and morality in combination, the custom having been for the last two centuries to discuss them separately .- Ref. Conversations Lexikon

DOGMAS, HISTORY OF, or, the History of Opinions, is a branch of ecclesiastical history which is more cultivated in Germany than here. "The history of cultivated in Germany than here. "The history o dogmas," says Neander, "traces the generic develop ment of Christian doctrine; it shows in what forms the ment of Christian doctrine; it shows in what forms the same Christian truth has been developed as doctrine, and the relation of these forms to one another and to Christianity itself. . . The history of dogmas is distin-guished from the history of Christian truth, as it stands in the original records, which is to be regarded as the peculiar province of New Testament theology, and especially of New Testament dogmatics. . . It is also bounded at another point by the representation of the condition of the Church at the present time, which is the business of statistics. The history of dogmas relates, therefore, to the development of Christian doc-trine in the intermediate period between pure apostolic Christianity and the church of the present day. object is to exhibit in an historical way the origin and the changes of the various Christian systems of belief, showing what opinions were received by the various sects in different ages of Christianity; the sources of the different creeds; by what arguments they were attacked and supported; what degrees of importance were attached to them in different ages; the circumstances by which they were affected; and the modes in which they were combined into systems. It is easy to see how important and interesting a study this is, teaching, as it does, modesty and forbearance in the support of particular opinions, by showing the vast variety of those which have afforded subjects of bitter controversy at particular periods, and have then passed away into oblivion. It shows farther, the process of culture which the human mind has experienced under the influence of Christianity, the conflict of truth with error, and the triumph of the former over the latter. The history of dogmas stands in very close connection with the history of the Church, and was formerly regarded merely as a department of it; but on account of its wide extent and importance, it is now generally treated as a distinct science. In church history, dormas are not noticed till their influence has been

periods then treated separately. Historians, however, differ greatly as to the number and limits of the different periods. The following are those adopted by Hagenbach :- 1. From the close of the Apostolic age to Hagenbach: —1. From the case of the Apologetics; the death of Origen (80–254),—the age of Apologetics; 2. from the death of Origen to John of Damascenus (240–730),—the age of Polemics; 3. from John Damascenus to the Reformation (730–1517),—the age of Systems (scholasticism in its widest sense); 4. from the Reformation to the abolition of the Formula Consensus in reformed Switzerland, and the rise of the Wolfian philosophy in Germany (1517—1720),—the age of Polemico-ecclesiastical Symbolism; 5. from the year 1720 to the present day,—the age of Criticism, of Speculation, and of Antithesis between faith and knowledge, philosophy and Christianity, reason and revelation.—Ref. Hagenbach's History of Doctrines; Neander's Lectures on Dogmas.

DOGMATISTS, dog'-ma-tists, were a sect of ancient physicians, called also Logici, or logicians, from their employing the rules of logic and reason in their pro-fession, as distinguished from the empirics. They treated medicine as a speculative science,—defining, dividing, laying down principles, and drawing conclu-sions. They reduced diseases to certain genera, and these genera to species, and furnished remedies for

them all.

them all.

Dorr, doyt (Du. dayt), a small piece of Dutch copper
money, in value the eighth part of a stiver, or half a
farthing. In Scotland, during the reign of the Stuarts,
the doit was the penny piece, twelve of which were
equal to a penny sterling. Shakspere, in "Coriolanus,"
makes allusion to it as a thing of the least value.

Dolog, or Dol., dol'-chai (Ital.), a term in Mus.,
used to denote that the passage over which it is written
is to be played in a soft, smooth, and delicate manner.

is to be played in a soft, smooth, and delicate manner. In instrumental music, this term is generally applied to those portions of melody which are so peculiarly adapted to the voice that the performer cannot express them better than by taking the vocal tones as his

Dole, dole (Lat. dolus, guile), a term used in Scotland, denoting the amount of conscious guilt or evil intention necessary to make a legal crime. It corresponds with the English term felonious intent. Doli incapax is one who is incapable of dole, or incapable of consent.

Dolertin, dol'-cr-ite, in Min., a mineral composed of felspar and sujike. It is a variety of greenstone.

Doles at Funerals, doles, an ancient custom of making gifts to the poor at funerals, which was in use making gitts to the poor at transrat, which was in use till comparatively modern times. It was continued until long after praying for the dead had been abandoned at the Reformation. The custom probably arose from the opinion that such gifts did give repose to the soul of the deceased. In Nichols's "History of Leicestershire" he thus speaks of the custom in connection with the village of Strathern.—"In 1790 there were 432 inhebitives the number takes by the latterners. inhabitants, the number taken by the last person who carried about bread which was given for dole at a funeral,—a custom formerly common through this part of England, though now fallen much into disuse. The practice was sometimes to bequeath it by will; but whether so specified or not, the ceremony was seldom omitted. On such occasions a small lost was sent to omitted. On such occasions a small lost was sent to every person, without distinction of age or circumstances; and not to receive it was a mark of particular disrespect." The practice of giving doles at funerals was not only common in England, but also in Wales, Scotland, and Ireland. By some the custom is traced back to the sin-offering amongst the ancient Hebrews.

Doll, doll (Welsh delor), a toy, shaped like the figure of an infant, used by children of both serse, but mostly by female children, whose love of dolls not only cultivates their affections, but teaches them to dogmas are not noticed till their influence has been greatly extended, while in the history of dogmas conflicting opinions are traced to their germ; the latter gropes its way to their hidden origin, the former only concerns itself with them as outward embroilments of controversy. The history of dogmas further for the transition from ecclesiastical history apart of the education of girls, whose natural instincts forms the transition from ecclesiastical history and love of nursing are exhibited from their tenderest age. The use of these little effigies dates from the the history of dogmas two methods of arrangement may be followed,—either the order of time, or according to the nature of the events. Each of these methods has its advantages and disadvantages, and generally the two are combined; certain epochs or of the Australian aborigines, the love of the imitation of the cares of maternity is equally implanted. The

## Dollar

majority of the dolls imported into Great Britain come from the Netherlands. The old Dutch or Flemish doll had a well-made face, a gaudy dress, and thin wooden legs. Great improvements have recently taken place in the manufacture of dolls, and large quantities are made in France, on the Bhine, and in Switzerland, as well as in England; and many hundred women are employed in their construction; some of whom carve employed in their construction; some of whom carve the faces, others the figures, others the limbs; another class of operatives paints them, and another prepares and puts on the dresses. In 1861 there were twenty-three master doil-makers in London, one of whom manufactured them entirely of gutta-percha. Wires and machinery have been introduced into the bodies of the dolls, that make them open and shut their eyes, and imitate the sound of the words "papa," and "mamma." Since the accession of the queen, blue eyes have been generally inserted in the heads of dolls in England; but on the continent and expensible in in England; but on the continent, and especially in Spain, black eyes are the favourites. In America, black dolls are made of gutta-percha, expressly for the use of negro children.

negro children.

DOLLAR, dol'-lar (Ger. thaler, Du. daulder), the name of a coin of the states of America, whose value in the scale of coins adopted is equal to 100 cents, 10 dimes, or ,; of an eagle. The American dollar, which was taken from the old Spanish dollar, or pisatre, was formerly only of silver; but since 1849, a considerable issue of gold dollars has taken place. The American dollar is estimated in exchange at 3s. 2d. sterling. The Prussian dollar, or thaler, is worth 3s. sterling: in other

dollar is estimated in exchange at 4s. 2d. sterling. The Prussian dollar, or thaler, is worth 3s. sterling; in other parts of Germany the value of the dollar varies.

DOLLY-SHOP, dol'-le, the name applied in London to a shop where rags, old articles, and refuse, are bought, and over the door of which is usually suspended a large black doll. Dolly-shops are often kept as cloaks for an illegal trade. A small sum is advanced upon articles, which the seller has the option of repurchasing a few days after at a higher price; and thus a large a few days after at a higher price; and thus a large profit is derived from a system of unlicensed pawn-broking.

DOLMEN, dol'-men, the name given by French archæologists to the monumental records crected over Celtic nurial-places in Great Britain and France, which are called connects in Great Britain and France, which are called connects in this country. (See Curnic Architecture.) The word is supposed to be the Celtic term for a stone table. The neighbourhood of Saumur, on the Loire, in the department of the Maine and Loire, is rich in Druidical remains, and one of the most respectable department that the source of the most respectable department. markable dolmens that are known is to be seen there. It is called the Pierre converte, and consists of a rude structure of four broad thick stones, covering an area of about sixty-five feet in length by fifteen in breadth, and supported on ten unlewn blocks about six feet

high.

DOLOMITE, dol'-o-mits (from Dolomieu, a French geologist), in Min., a crystalline variety of magnesian limestone, differing from the ordinary varieties, which are compact and amorphous. The crystalline structure is generally supposed to result from igneous influence a Dolumin, dol'gin (delphims).—This fish bears a great resemblance to the porpoise, but has a much longer and sharper smout. The teeth in both jaws are nearly conical, though some of the species lose those of the upper jaw at an early age. They are very vo-

DOLPHIN.

racious, and are said to prey not only on fishes, medusæ. &c., but also on the wounded and feeble of their dusg. &C., Dut uses on the wounded and feeble of their own species. They live, however, in herds, which often delight the voyager in the ocean solitude by the gambols which they perform around his ship. "They may be discovered," says a celebrated naturalist, "at a great distance, as they are continually leaping from the great distance, as they are constituently coupling at one the surface of the sea, an action which, as it seems to have no obvious object, is probably the mere exuberance of animal mirth. When a shoal is seen thus frolicking at

## Domesday Book

the distance of a mile or two, in a few moments, having caught sight of the ship, down they come trooping with the velocity of the wind. When arrived, they display their agility in a thousand graceful motions,—now leap-ing with curved bodies many feet in the air, then darking through a wave with incredible velocity, leaving a slender wake of whitening foam under the water; now the thin back fin only is exposed, cutting the surface like a knife; then the broad and muscular tail is elerated as the animal plunges perpendicularly down into the depth, or dives beneath the keel to explore the oppo-site side." It is said that in these gambols the dolphin has been known to leap out of the water to such a height as to fall on the deck of a ship.

height as to tail on the deut of a sing.

Dom. (See Don.)

Dom.noc. (See Doomnoon.)

Dome, dome (Gr. doma, Lat. domum, Ital. duomo, a house; but, in the last-named language, applied to cathedrals and churches, as the house of God), in Arch. thedrals and churches, as the house of God), in Arch., a word which expresses any covering placed over a building and taking the form of a hemisphere or spherical vault, whether round or polygonal, at the base. A distinction should properly be made between the terms dome and cupola,—the former applying to the exterior, or convexity of the covering, and the latter to its interior surface, or concavity; but they are generally used as synonymous expressions. In building a dome of masonry, its thickness should be the greatest at the base, which is the weakest part, and gradually diminish towards its crown or centre. The lower courses of masonry should also be strengthened by hooping or framing, particularly if the diameter of by hooping or framing, particularly if the diameter of the base be considerable. The principles on which the equilibrium of a dome is maintained are similar to those on which the equilibrium of arches depends. (See EQUILIBRUM OF ARCHES.) They are put toge-ther on centerings of elaborate construction; but these serve rather as a scaffold for the workman than as a support for the materials of which the dome is made, until the crown is inserted. The use of the dome was not resorted to by the Egyptians, Assyrians, and Greeks; but the Romans, who were the first to use the arch to any great extent, also erected circular vaulted roofs or domes over many of the temples of their heathen gods; among which may be named those of Bacchus, Apollo, Minerva, and Diana, and the mag-nificent Pantheon at Rome. They also covered the chambers of some of their splendid baths with roofs built in this form; as in the baths of Caracalla and Diodetian. In Byzantine architecture, the dome was a peculiar feature in all cathedrals and churches built after that style, and amongst these the dome of St. Store that style, and amongst these the dome of St. Sophis, at Constantinople, may be especially noticed. (See BYZANTIES ARCHITECTURE.) The majority of the Italian churches built during the middle ages are also surmounted by domes. The great dome of St. Peter's at Rome was designed and partly built under the superintendence of Michael-Angelo. Among the most remarkable dense of more modern construction most remarkable domes of more modern construction may be mentioned those of the Invalides and the Pantheon at Paris, and those of St. Paul's, by Sir Christopher Wren, the reading-room of the British Museum, and the Exhibition building of 1862, in London. The following are the dimensions of some that have been already mentioned, with one or two additions, giving the height in feet from the base to the centre, and the diameter of the base, including the thickness of the walling or materials between the outer and inner sur-

the most ancient and valuable records of England, framed by order of William the Conqueros, to serve as the register from which judgment was to be given upon the value, tenure, and services of lands therein described. According to some historians, the curve was the class of the conditions of the con begun in 1080 or 1083; according to others, at the close of 1085. The book itself records its completion in 1086. The work appears to have been known by the other names of Rotulus Wintoniae (Roll of Winchester), Liber de Wintonia (Book of Winchester, in cousequence of its being at one period preserved in that city), the Liber Censualis Anglia (Rate-book of England), Scriptum Thessuri Regis (Record of the King's Treasury). The origin and object of the record are best described by the author of the "Saxon Chronicle," a contemporary work. He states, that in the nine-teenth year of the Conqueror's reign an invasion was apprehended from Denmark, and the military consti-tution of the Saxons being then laid aside, and no other introduced in its stead, the kingdom was wholly defenceless, which occasioned the king to bring over a large army of Normans and Britons, who were quartered upon every landholder, and greatly oppressed the people. But the danger having passed away, the king held a council, to inquire into the state of the nation; the immediate consequence of which was the compila-tion of the "Domesday Book," or Great Survey, which was finished in the succeeding year, at which period the king, attended by all his nobility, held a court at Sarum, where all the principal landholders submitted their lands to the yoke of military tenure, became the king's vassals, and did homege and fealty to his person. The formation of the record took place thus : persons called the king's justiciaries visited the greater part of the kingdom and obtained the required particulars, on oath, from the sheriffs, lords of manor, parish priests, reeves of hundreds, bailiffs, and villeins of each vill. The record contained a list of the bishops, churches, religious houses, great men, king's manors, king's tenants in capite, and under-tenants; the particu-lars of the name of each place, its holder, its extent, the extent of wood, meadow, and pasture, the ponds and mills, the quantity of live stock, the value of the whole, the homages of each manor, the number of villeins, cotarii, servii, and freemen, and how much each freeman or socman had. Three estimates of the estates were made; viz., as they were in the time of Edward the Confessor; as they in the time of Laward the Contessor; as they were bestowed by William, and as they were at the time of the survey. Moreover, the juriors were required to state whether any advance could be made in the value. The returns of the justiciaries were sent to Winchester, and being there digested, were entered in two volumes, which were carried about with the king and great seal, or deposited in a chapel or vault of the cathedral, called domus Det. From this last circumstance the name Domesday is thought to be derived; while others ascribe it to a parallel between the de-cisions of the book and those of the day of doom. The first volume, called the "Great Domesday, of 382 folio pages, closely written on vellum, and conor 382 folio pages, closely written on veilum, and contains the survey of thirty-one counties. The second, cr "Little Domesday," is a quarto volume of 450 pages, and comprises the returns from Essex, Suffolk, and Norfolk. It contains also a list of "invasions," or lands possessed without royal authority. Neither Northumberland, Cumberland, Westmoreland, nor Durham, appears in the record; for which various reasons are accorded. Other counties are described either whells. assigned. Other counties are described, either wholly or in part, under adjacent divisions. No account is given of either London or Winehester. As a census of the population, the Domesday Rook is of a constant. the population, the Domesday Book is of no value; but with regard to the ancient tenure of lands its authority is supreme. It mentions only 1,400 tenants in capite. and 8,000 under-tenants, and names a total population of 292,242. The book is now preserved in the chapter-house at Westminster. A fac-simile of it was published house at Westminster. A fac-simile of it was published in 1783 by order of the government. It was ten years in passing through the press. In 1816 the commissioners of public records published two supplementary volumes, with a valuable introduction by Sir Henry Ellis. The first volume was taken up with the general introduction; the second volume contained four similar records as the Demeaday; viz., the Econ Domesday, and the the Inquisitio Eliensis, the Winton Domesday, and

the Boldon Book. These last records were valuable, as tending to supply what was deficient in the older and more famous Domesday-book. It is under contemplation to publish a fac-simile edition of the record.

DOMESTIC ARCHITECTURE, do-mes'-tik (Lat. domestious) .- The domestic architecture of every nation is eatly influenced by the degree of civilization to which it has attained, the climate and situation of the countries and quatoms of try, the national and social manners and customs of the people, and the materials for building which can be most readily procured. In any case, the external appearance and architectural design of any dwellingspectance an architectural design of any aventury, house, whether it be a palace or a cottage, should be adupted to its local position, being mainly governed by the surrounding scenery, the materials that may be at hand, and sometimes by the style of the houses that may be in juxtaposition with it; while the internal arrangements must be controlled in a great measure by the circumstances, habits, and position in life of the family for whose occupation it is intended. But in dwelling-houses of an ordinary class, however desira-ble architectural display and ornamentation may be when judiciously used, it is necessary that the comfort and convenience of the interior should be regarded before the external appearance, particularly when the builder is limited in his outlay; and the money which is too often wasted on the decoration of the outside should be spent in making the sleeping apartments a foot or two higher, and the attics less confined in space. The chief points to which attention should be paid in choosing a site for a house and erecting the building have been mentioned elsewhere. (See BUILDING.) To enter into details on a subject that occupies so great a range, and involves so many points that are worthy of consideration, would be manifestly impossi-ble; and it would be equally fulle to attempt to point out any particular style of building, as regards the exterior or frontage, or any method of arranging the interior, when so many matters have to be thought of that directly refer to the locality in which the building is to be erected, and the purposes which that building may be intended to serve. It will be sufficient, therefore, to direct the reader to those works which will give him an insight into the form of English houses since 1100 to the present time, at different periods of our history; and the most suitable hints for the erection and design of houses, whether for private residences or for business purposes, either in town or country. Fig. 1, Plate XL., is the elevation of a baywindow on the ground-floor, in the Domestic Gothic style. Fig. 2 of the same plate is a front elevation of

principal door to a house in the same style.

DOMICILE, dom'e-sile (Lat. domicilium, from domus, a house), in Law, is the place where a person has his home. What constitutes a man's domicile in a legal sense is a question that has given rise to many difficul-ties, and is marked by many subtile distinctions. In general, a man's domicile is "where he has placed his hearth and centred his fortunes." The domicile of the parents is that of the child; and if a child be illegiumate, it follows the domicile of its mother. A married woman follows the domicile of her husband, and a widow retains the domicile of her late husband till she acquires another. A married man's domicile is generally taken to be where the residence of his family is; and in general the place where a man lives is to be taken as his domicile, unless there be evidence to the contrary. Every person of full age who removes from one place to another with the intention of making the latter his permanent residence, constitutes it his domi-cile; but it is held that the former domicile is not lost till the new one is acquired animo et facto. It is an established principle of the English law that domicile of origin must prevail until the party has not only acquired snother, but has manifested and carried into execution an intention of abandoning his former domi-

#### Dominican Friars

proprietor may have taken place. A will, to be valid, must be executed in conformity to the law of the country where the testator was domiciled; and the realidity of a marriage depends upon its being in conformity with the law of the country in which it took place, provided the parties were bond fide domiciled

DOMINICAN FUIARS, dom-in'-c-kan, an order of friars first instituted by Dominic de Guzman, at Toulouse, in 1215. About the year before he had, together with Diego de Azebes, endeavoured to convert the Albigeness in the south of France by preaching. Feeling that the immorality of the clergy and the ignorance of the population were great aids to heresy, he instituted the order of the Dominicans for the purpose of preaching and converting. The order was confirmed by Innocent III. and Honorius III., in 1216. Before that time, however, Dominic had found that preaching had little effect upon the Albigenees; and, at his instigation, the pope proclaimed a crusade against the "heretics." barons of France were summoned to join, and horrible slaughter was committed on these unfortunate people. Dominic himself is not said to have been a harsh or cruel man, but merely led blindly away by bigotry and religious passion. The members of his bigotry and religious passion. The members of his new order wore a white garment similar to that worn by the Carthusians, with a black cloak and a pointed black cap. Five years after their institution they took Diack cap. Five years after their institution they fook the vow of poverty, and in the following year Dominic died. He was canonized by Gregory IX. in 1233. Another Dominican order was established in 1224, called the Knights of Christ. Its object was to suppress heresy by force of arms. The title of the order was afterwards changed to that of the Penitents of St. Dominic. rights and privileges. The original order increased rapidly in numbers and influence. Within six years Within six years after their institution they had spread into England, led by Gilbert du Fresney, and founded a monastery at Oxord. They also made their way into Scotland, where they were well received by Alexander II. In England they were always called the Black friars, and many traces of them are to be observed in nearly every town. In France they were called Jacobins, from the fact that they first located themselves in the Rue St. Jacques,—in the Latin, Jacobus. They the Rue St. Jacques,—in the Latin, Jacobus. They produced several famons scholars; Albertus Magnus, Thomas Aquinas, and Raymund de Pennaforte, being amongst the number. Their great rivals were the Franciscans. At the present day, the order of Dominican sonly flourishes in Italy, France, Hungury, Switzerland, and America. Dominican uns have also existed contemporaneously with the friars. There are several of their convents on the continent,

Domino, dom'e-no, a long robe of black silk furnished with a hood removable at plensure, and used as a dis-guise by persons of both sexes, chiefly at masquerades. The name domino was doubtless derived from the habit worn by the priests upon their heads and shoulders during winter; from whence sprung the association with a word frequently occurring in the liturgy of the

Roman Catholic church.

DOMINORS, a game generally played with twentyeight flat oblong pieces of ivory or bone, each divided by a line into two parts, bearing numbers marked by points. The game is won by the player who plays out all his tablets or dominoes first, or, if that is impossible, the player who has the least number of points on the dominoes left in hand. The game of dominoes is sup-posed to be very ancient; it has been traced back to Greek, Hebrew, and Chinese origin. At the beginning of the 18th century it was introduced into France from

of the 18th century it was introduced into France from Italy, and, after becoming very popular there, it spread into Germany and generally over the continent.

Don, don (from the Lat. dominus, lord), a title of honour in Spain and Portugal. In the latter country no person can assume the title of don without permission from the king. This mark of distinction and nobility was first conferred upon Pelayo, in the beginning of the 8th century. It is frequently found in the works of Chaucer, under the old English form of the work don.

of the word, dan.

Donari's Comer, do-na'-le, a brilliant comet discovered at Florence by an Italian astronomer, named

#### Donatists

be nearly 230,000,000 of miles distant from the earth. It became visible to the naked eye in the beginning of the September following, reaching its perihelion about the 30th of that month. It reached the point in its orbit nearest to the earth on Oct. 10, when the diameter of its head appeared to be about 100,000 miles, and that of the nucleus 800 miles. When it first became visible without the aid of a telescope, its tail appeared to be 14,000,000 of miles in length, gradually increased to 51,000,000 on Oct. 10, the tail seemed to cover an arc of 40°; but as it went away from the earth, the length of this part of the comet diminished with greater apparent rapidity than

it had previously increased.

DONATION, do-nui-shun (Lat. donatio, from done, I give), is the act of giving or bestowing; also, a gift. A donation, to be valid in law, supposes a capacity both in the done to give and in the done to receive. It distinguishes between a donation into the done. the donor to give and in the donee to receive. It dis-tinguishes between a donatio inter vivos and donatio mortis causa; in the former case a gift, to be valid and binding, must either be accompanied by the solemnity of a deed, or by that of delivery of possession; and when so perfected it is not in the donor's power to retract it, though a mere gift, unless it be prejudicial to creditors, or the donor were under some legal inca-pacity, as infancy, coverture, or the like. A donatio mortis causa is when a person in his last sickness, apprehending his dissolution near, delivers, or causes to be delivered, to another the possession of any personal goods to keep in case of his decease. The gift being made only in contemplation of death, implies that if the donor lives, it shall revert to himself, and consequently it partakes of the nature of a legncy. If the donor dies, it needs not the assent of the executors, but it is of no avail against creditors in case of a deficiency of assets. To be effectual, it must be accompanied by a delivery of the chattels; or if it be in action, and not in possession, the delivery of the instrument by which it is secured. As it takes effect from the delivery, it is not a testamentary act, and does not come within the jurisdiction of the ecclesiastical courts, nor require probate or administration.

DONATISTS, do'-na-tists, in Eccl. Hist. was the name of a powerful and influential Christian sect that arose of a powerful and industrial Cursulan sees unas arose in North Africa in the early part of the 4th century. They were the followers of Donatus, a bishop of Nunnidia, who opposed the election of Cecilianus to the bishopric of Carthage in 311, on the ground of his being a traditor, or having delivered up the sacred books to the nagara and that thousand is alaction, we books to the pagans, and that thereby his election was void, and all who adhered to him heretics. He quitted vois, and an who adhered to him heretics. He quitted the Roman church, and founded a distinct sect, re-garded all others as heretics, and not to be received into their body without a second baptism; conse-quently they denied the infallibility of the Roman church. They were condemned in a council held as Roma two years of their assumptions and the Rome two years after their separation, and the year following by another at Arles. Constantine the Great, in 316, deprived them of their churches, and sent their seditious bishops into banishment; but, notwithstanding these severities, their doctrines spread very rapidly, and in 330 they are said to have numbered 172 bishops in the Christian provinces of Northern Africa. Driven in the Christian provinces of Northern Africa. Driven fanatical by the oppression of the civil power, they not only denied the right of the state to interfere in matters ecclesiastical, but bands of Donatist ascelies attacked the imperial troops, and for thirteen years continued to devastate Mauritania and Numidia. Martyrdom was eagerly sought by them, and they willingly gave themselves up to be executed. Neither the eloquence of Augustine nor the severities of the emperor. Honoxing that any marked effect upon the emperor Honorius had any marked effect upon this body, and they continued to flourish during the 5th and greater part of the 6th century. Towards the end of the 6th century, however, many of them were induced to return to the Catholic church, and in the following century they became extinct. The Donatists, like the Novatisns, went upon the principle that the essence of a true church, according to Epiesians v. 27, consisted in the purity and holiness of each of its members individually, and not merely in its Apostolico-Catholic foundation and teaching: hence they held. DONATT'S COMET, do-nat-fe, a brilliant comet dis-covered at Florence by an Italian astronomer, named was itself polluted by communion with them, and con-Donati, early in June, 1839, when it was supposed to sequently ceased to be a true Christian church. They

### Donative

therefore excommunicated all known and gross offenders, only receiving them again upon being re-bap-tized: and they also held that the efficacy of the sacraments depended upon the personal worthiness of

the administrator.

the administrator.

DONATIVE, don'-d-fiv (Lat. donatives), is generally a donation, gift, or gratuity. In the canon law it is applied to a benefice given by the patron to a priest without presentation to the ordinary, and without is attitution and induction. No license from the bishop is necessary to perfect the donee's title to the possession of the donative; it receives its full effect from the single act and sole authority of the donor. Donatives are further exempt from episcopal jurisdiction, and are wisited by commissioners appointed by the patron. Donatives are created whenever the king, or any subject by his license, doth found a church or chapel, and ordain that it shall be merely in the gift or disposal of ordain that it shall be merely in the gift or disposal of the patron, subject to his visitation only, and not to that of the ordinary, and vested absolutely in the clerk by the patron's deed of donation, without presentation, institution, or induction. According to some, this was anciently the only way of conferring ecolesiastical be-neffices in England, the institution by a bishop not being earlier than the time of Becket; according to others, the claim of the bishops to institution is as old as the first planting of Christianity in the island. The law now is, that if the true patron once waives his privileze now is, that if the true patron once waives his privilege of donation, and presents to the bishop, and the clerk is admitted and instituted, the advowson ceases ever

is admitted and instituted, the advowson ceases ever after to be donative.

Donis Conditionalists. (See Entail.)

Donion, or Dongeon, don'-jon (Fr. donjon), in Medimval Arch., the name given to the keep or principal part of a castle. (See Castle.) Prisoners were generally confined in the basement story of the donjon, and from this circumstance, the word, which is now written dungeon, has been taken to express any dark and dreary prison cell, but more particularly one which is partially or entirely below the surface of the ground.

and areary prison cell, out more particularly one which is partially or entirely below the surface of the ground. Dow Juan, don ju'-ān, a legendary or mythical character, prevalent in southern Europe, and intended as a representative cubodiment of sensuality and want of faith. It stands in contrast to Göthe's Faust, which represents rather a crafty and subtle rationalism tending towards the same ends. The rationalism tending towards the same ends. The legend of Don Juan represents the hero as a profligate man, who gives himself up entirely to his own selfish pleasures, especially to that of love. The legends are numerous, but bear a close resemblance to one another. The principal events are as follows. The scene is laid at Seville, and Don Juan is represented as belonging to a high and celebrated family. His chief object is the seduction of the daughter of a governor at Seville. Finding that the father opposes his designs, he stabs him in a duel. Afterwards, forcing his way into the family tomb of the murdered man, he orders a feast to be laid out, and sneeringly invites the marble statue which had been raised to his victim to join him at the banquet. The statue does appear, and, seizing Don banquet. The statue does appear, and, seizing Don Juan, both of them sink together into hell. This negend, which has been much used, was first employed in an operatic form by Vincenzo Righini, in "Il Con-vitato di Pietra." Mozart's "Don Juan" was written

witato di Pietra." Mozart's "Don Juan" was wruten eleven years afterwards, and since that time (1787) the legend has been a general favourite.

DONTH, REGIUM. (See REGIUM DONUM.)

DOOM BOOK, DOM BOC, Or DOME BOOK, doom'-buk, is the name given to the code of laws compiled by Alfred the Great. The general opinion has long been than the code of the laws but, according that Alfred was the framer of these laws; but, seconding to Dr. Pauli, in his life of that monarch, "he ing to Dr. Pauli, in his life of that monarch, "he created no new laws; his aim was simply to restore, to removate, to improve." In every part of his dominions he met with existing laws which required revision, alteration, or arrangement, and to this duty Alfred addressed himself, assisted by the advice and co-operation of the wisest and best men of the time. He had before him the Kentish collection of Rhelbert, the carvillation of the Wast Sayno laws by his own ancestor. compilation of the West Saxon laws by his own ancestor and the law-book of the great Offs, which was used derois. "Ina's collection was the only one rein Mercia. ceived entire into the Codex, which was chiefly applicable to the condition of the West Saxons. A few articles were admitted here and there from the Kentish

### DOORWAY

and Mercian laws; but research into this matter is not possible, as Offa's book is lost."—(Pauli.) Every-where throughout this code is the character of Alfred's own mind shown much more than that of the age in which he lived. It cannot be denied that there is a tendency towards despotism manifested in these laws, and also that they incline too much to the old Levitand also that they incline too much to the old Levitical law; but nevertheless it is evident that he strove to administer law and justice with equity, and to temper the old Jewish economy by the addition of the grand Christian doctrine, that "a man should love his neighbour as himself." He begins with extracts from the Bible:—"And the Lord spake all these words; saying, I am the Lord thy God," &c.; then follow the Ten Commandments, part of the Mosaic law, followed by passages from the New Testament, including the golden rule of Christian morality. He strove not only to represe grime but to check every species of impogomes rue of christian morality. He acrove not only to repress crime, but to check every species of immo-rality among all classes of his subjects; and his efforts to educate the morals of his powerful but still uncul-tivated people, in accordance with the doctrines of the Bible, are indeed beautiful and excellent.

Doomstar, or Deemstar, doomster, the name of an officer formerly attached to the High Court of Justiciary in Scotland. He pronounced the sentence or doom of condemned persons. The office has been abolished for many years. When a trial had conor doom of condemned persons. The office has been abolished for many years. When a trial had concluded, the doomster was brought forward face to face with the wretched criminal. In the "Heart of Midlothian" and "Old Mortality" this dread official is described with all Sir Walter Scott's graphic power. Deemsters, in the islands of Jersey and Man, are judges of a particular kind.

Doon, dore (Sax. dure, Tenton. deur), the movable panel by which the doorway or entrance to any building anartment descriptor are the face. The movable of the same and t

panel by which the doorway or entrance to any building, apartment, closet, or court, is closed. The most common kind of door consists of boards joined together and nailed to transverse slips of wood. Such doors as these are called "ledge-doors." They are hung on staples, and fastened by a latch: they are principally used for workshops, out-houses, offices, and walled gardens. The ordinary house-door is fastened to one side of the doorway by hinges (see HINGE), on which it swings. It is secured by a box-lock, fixed to the inner side, or by a mortise-lock, which is buried in the lockrail, and worked by handles projecting on either side. rail, and worked by handles projecting on either side. These doors are made of panels fixed in a solid frame-These doors are made of panels fixed in a solid framework, and finished by mouldings of different kinds, which surround the panel. The horizontal pieces of the frame are called "rails," and the vertical pieces "styles." Doors are technically described by the number of panels they contain and the kind of moulding with which they are finished. When they move on hinges, like the ordinary doors of apartments, they are termed "swing-doors" Large double doors used to separate any long room are called "falling-doors". termed "swing-doors" Large double doors used to separate any long room are called "folding-doors." A jib-door is a door in a wall, which cannot well be detected when closed. A rolling or sliding door is one which travels on rollers, or in a groove, parallel and close to the wall in which is the sperture that it is intended to close. A smaller door which closes an opening cut in the entrance-door of a court-yard or large building, is called a "wicket-door." A trap-door is a door cut in called a "wicket-door." A trap-door is a door out in the floor to give access to cellars, or open parts under the roof of a house. Doors of large public buildings are sometimes made of brass, and even of stone or marble.

DODMAY, dore'-way, an aperture in the wall of any building, or the partitions, to allow of ingress and egress to and from the building itself and the various spartments that are within it. In ordinary buildings a strong framework of wood, to which the door is hung, is fastened to bond-timbers inserted in the sides of the is tastened to bond-timbers inserted in the sides of the opening. The vertical pieces or sides of the framework are called the "jambs," and the transverse piece at the top "the lintel." A piece of wood called the "cill" is sometimes put transversely between the feet, or lower ends of the jambs, to give strength and stiffness to the framework. For entrance-doors the cill is generally of stone. The framework is finished round the adder that the contract of the edge that is nearest the wall of the room or passage by a moulding. Doorways vary according to the size and importance of the building or apartment to which they give access, but the dimensions of an ordinary door-

## Dorado

way are about 7 feet by 3 feet. The treatment of the doorway forms a striking characteristic feature in the various styles of architecture. In Egyptian and Assyrian architecture the doorways are surmounted with square lintels. The openings, particularly in the former, were wider at the bottom than at the top, and surrounded by a flat moulding enriched with sculpture. The lintel was generally very deep, and surmounted with a projecting cornico, and colossal figures were usually placed on either side of the opening. The door-ways in Grecian architecture were rectangular in form; they were surrounded by mouldings, and sometimes surmounted with a cornice supported on brackets. In early Roman architecture the form of the doorway was the same; but at a later period the semicircular arched heading was introduced, which subsequently became the characteristic feature of the Byzantine and Romanesque styles. In Arabian and Gothic architecture the head of the doorway assumed a pointed form, and in the latter the opening was surrounded by a great variety of bold and deep mouldings, and richly orna-mented. The decoration employed became more and more elaborate in the transition from the Norman style to the Perpendicular English, through the Early English and Decorated English periods, being, perhaps, most graceful and natural in the style last named. In the Perpendicular English style of architecture, the doorway, although it was still pointed, was surmounted by a square moulding or label, which is peculiar to buildings in this style and of the Tudor period, when the flat four-centred arched heading was introduced.

DORADO, do-ra'-do (Fr. dorade, Sp. dorado, gilt, from dorar, to gild), in Astron., a constellation in the southern hemisphere, otherwise known as the Swordish, and so named by the German astronomer Bayer. It lies in a direct line between the constellations Argo and Eridanus. Its largest star is of the third magnitude.

Dorcas Society, dor'-kds, a term applied to an association of ladies who unite together to obtain subscriptions in order to bestow clothing and other aids to families in distress and want. The name is also given to societies got up for the purpose of giving work to distressed needlewomen. The name owes its origin to a verse in the Acts of the Apostles. "And all the widows stood by him weeping, and showing the

conts and garments which Dorcas made, while she was

with them."—Acts ix. 39.

DORIC DIALECT, dor'-ik, was one of the four dialects of the ancient Greek language, being that spoken by the inhabitants of Doris. It was characterized by a certain roughness and harshness, and was much less polished than either the Ionic or Attic. Pindar, Theoccitus, and Bion wrote in this dialect.

Dorss, dor-is, a genus of naked marine mollusca, sometimes known as sea-lemons. The body is oval, the abdomen flat; the back flat in some, and elevated in others; the mouth a small proboscis, with two small proboscis, with two small proboscis. tentacula; the vent situated in the back, and surrounded by a circle of branched or plumed gills. As is obvious from the structure of the digestive organs, the species must exist on the softest food. They are plentiful on the coasts of Britain, where they may be found crawling on rocks, sea-weed, &c.

DORMANT, dor'-mint (Fr., sleeping), in Her., an animal is said to be dormant when it has its head resting upon its fore-paws, in contradistinction to couchant,

ing upon its fore-paws, in contradistinction to conchant, where the head of the animal is held erect.

DOBMART VITALITY. (See VITALITY.)

DOBMER, dor-mer, the name given to a window put in a small projection like a gable rising vertically from the roof of a house, and used to light attice or sleeping apartments in the roof, instead of a skylight, which is in the plane of the roof. There are sometimes three, and even four rows of dormer windows in the steep roofs of large public edifices built in France, Belgium, Holland, and Germany, between the com-mencement of the 15th and the close of the 17th century.

Domitory, dor-me-tor-s (Lat. dormirs, Fr. dormir, to sleep), a sleeping-chamber, but especially applied to large apartments in a moreastery or school calculated to hold agrent number of beds. To insure privacy and solitude, either side of the dormitory in religious houses was often divided into a number of small cells. Dort, Synod of

DORNOUSE, dor'mous firm Lat. dormio, I sleep, and mouse), a gen. of rodent quadrupeds, which is generally regarded as forming a connecting link between the Murida (rats, mice, &c.) and the Sciurida (squirrels, &c.). The chief characters by which the dormice are distinguished from the squirrels are derived from the structure of the skull, teeth, and intestine. The form of the skull resembles that of the mice, in being suddenly narrowed in the frontal region. There are four molar teeth on each side in each jaw; the upper jaw not possessing the anterior rudimentary fifth molar characteristic of the squirrels. The intestine is destitute of a cocoum,—an organ which is of very large size in all the other rodentia. The dormice have no check-pouches. The ears resemble those of mice. The body is about the size of that of the common mouse, but much plumper; the eyes large, black, and prominent; the tail between two and three inches in length, and more hairy at the top than elsewhere. With the exception of the throat, which is elsewhere. With the exception of the throat, which is white, the dormonse is of a tawny-red colour. They are found only in the temperate parts of the Old World, especially in Europe and Africa. In Asia they appear to be confined to the neighbourhood of the Caucasus. Only a single species, the common dormouse (Myozus aveldanarius), is found in Britain. It is extracted accelerated and decide the cardon of the caucast of the extremely gentle and easily tuned, and feeds on beech-mast, acorns, hazel-nuts, &c. "It takes its food hold-ing it in its hands, and sitting on its haunches like a squirrel (so do the rats), and often suspending itself by its hind feet, in which position it feeds as easily and its hind feet, in which position it feeds as easily and comfortably as in the most ordinary position. Towards the winter it becomes exceedingly fat, and, having laid up a store of food, retires to its little nest, and coiling itself up into a ball, with the tail over the head and back, becomes completely torpid. A mild day calls it into transient life; it then takes a fresh supply of food, and relaxes into its former slumber; and, finally awakening in the spring, by which time it has lost much of its fat, it enters upon its usual habits, and the enjoyment of the conjuval and natural affections. The much of its lat, it sheets upon its usual markets. The conjoyment of the conjugal and paternal affections. The young are generally born blind; but in a few days the eyes are opened, and in a short time they are enabled to seek their food independently of their parents' care. I have reason to believe, in some cases at least, the dormouse has a second brood early in the autumn, as 1 have received from one locality in the month of September an adult one about half grown, evidently of the spring brood, and three very young ones, not more than a fortnight or three weeks old."—(Bell's Brilish Quadrupeds.) There are two other beside the common dormouse; viz., the fat dormouse (Myozus Nitela). The former is a large species, as big as a rat, and with a tail like a squirrel. It is a native of France and the south of Europe. The garden dormouse is smaller than the fat dormouse, and, breeding in gardens, is very destructive to wall and other fruit. It is a native of the temperate parts of Enrope and Asia.

Dossar, dor'sail (Lat. dorsalis, from dorsum, the back), denotes something appertaining to the back, and in Anat. it forms part of the name of ligaments,

In Aust. Torms part of the name of agaments, arteries, &c., belonging to that region.

DORSTENIA, dor-ste'-ne-3 (in honour of Theodore Dorsten, a German botanist), in Bot., a gen. of plants belonging to the nat. ord. Moracea. The rhizomes and roots of several species have been supposed to be antidotes to the bites of venomous reptiles: those of D. con'rayerca and braziliensis have been employed in medicine for their stimulant, tonic, and disphoretic properties.

DORT, SYNOD OF, dort, a famous assembly convened in 1618 at Dort, or Dordrecht, on the Rhine, convoked by the authority of the States-general. Eminent divines from England, Scotland, Bremen, Hessia, Switzerland, the Palatinate, and the United Provinces, attended it to decide the controversy between the Arminians and the Calvinists. The Arminian party desired to begin the debate by a condemnation of the Calvinistic tenet of reprobation; but it was decreed that as they them. selves were accused of departure from the faith, before they could condemn others they must justify them-selves. To this order of procedure they would not yield submission. They were banished, and the synod condemned, in order, the Arminian tenets. The Ar-

Dory

minians, or, as they were sometimes called, the Remonstrant party, suffered civil prescription and cruel persecutions. Grotius was sentenced to perpetual impersonuous, and Oldenbarnevelt was executed. Fries-land, Groningen, Zealand, Guelderland, and Utrecht, would not accept all the decisions of the synod; and its authority was not fully recognized in Holland or England. (See Arminians and Calvinian.)

DOER, or JOHN DOER, dor'e, a native of the Mediterranean, Northern, and Atlantic seas. Torbay, on the western British coast, is a celebrated locality for this fish. Its name John Dory is probably derived form its French appellation, jaune (yellow) doree (gitt). It is naually about eighteen inches in length, though Pennant mentions one that weighed twelve pounds. The general surface of the body is smooth and destitute of scales, but spiny scales or bony shields guard the dorsal and ventral edges. The anterior portions of the dorsal and oval fins are spiny, and very listing the accurated from the simpless portions. It is distinctly separated from the spineless portions. It is an extremely voracious fish, preying on small fishes and their spawn, as well as on the various kinds of crustaces and marine insects. It has an oval black spot on each side, and on this account shares with the spot of each side, and this account states with the haddock the honourable repute of being the fish from whose mouth the tribute-money was taken by St. Peter, the impression of whose thumb and foreinger remained to record the event. Other species of the clory very similar to the European are found in the acas of other parts of the world. It is the type of the fam. Zeidæ. The scientific name of the British spefam. Zeidæ. The scies is Zeus Faber.

Dose, dose (Gr. dosis, from didomi, I give), is employed to denote a proper quantity of anything to be given or administered at one time, and is generally applied to medicines. As the quantity of any medicine proper to be administered to an individual must necessarily depend upon his age and strength, these have to be taken into account in determining in any case the proper dose. A certain quantity, known as a full dose, is usually fixed upon as being suitable for a male from is usually fixed upon as being suitable for a male from 25 to 40 years of age, diminishing proportionally for persons above or below that age. Thus, when the age is between 1 and 2 months, \( \frac{1}{2} \), to \( \frac{1}{2} \), of a full dose is aufficient; at 8 months, \( \frac{1}{2} \); 12 months, \( \frac{1}{2} \); 2 years, \( \frac{1}{2} \); 8 years, \( \frac{1}{2} \); 8 years, \( \frac{1}{2} \); 8 years, \( \frac{1}{2} \); 65 years, \( \frac{1}{2} \); 80 years, \( \frac{1}{2} \); 65 years, \( \frac{1}{2} \); 8 years and upwards, \( \frac{1}{2} \). Hesides age, there are frequently other eigenvalues to be taken into account: as the conwards, 3. Desacts age, there are required out-circumstances to be taken into account; as the con-stitution, habits, &c., of the individual; and usually abent one-fourth less should be given to an adult female than an adult male. Neither will the above rule apply to all medicines; for some naturally act more powerfully on children than adults, or vice versal.

more powerfully on children than adults, or vice versal.

Dor, dot (derivation doubtful), in Mus., a point placed after a note to increase its duration one half. Formerly the dot was called the point of perfection; because a note, when dotted, attained its greatest length, or, in other words, was perfected. Dotted motes are also termed notes of prolation.

Dorren Notes, dot'-ted, notes which are increased in length by the addition of dots placed after them. A dot placed after a note renders it half as long again. Thus, inasmuch as a semilorer is as long as two minims. A dot placed after a dotted semilorer is as long as two minims.

so is a dotted semibreve equal to three minims. A double dot placed after a note increases it to threefourths its original value: thus, a double-dotted semibreve would be equal to three minims and a half. Rests may also be increased by the addition of dots: thus, a dotted semibreve rest is as long as a semibreve and a minim rest. A double-dotted rest is lengthened in the same manuer as the sound of a double-dotted note. Double dots are rarely affixed to semibreves or minims. When dots are placed at the sides of double bars, they indicate that the portions on the dotted sides are to be repeated. They are sometimes attached to single bars for precisely the same purpose.

DOTTERE, dot-fur-el (Charadria moriellas), a species of plover inhabiting the northern parts of Europe and Asia. They delight in the high elevations. On the Helvelyn, in Cumberland, 3,055 feet above the level of the sea, they abound in vast numbers, as they do, likewise, on some of the highest mountains of Scotland. They are migratory, and appear in Britain on their northern migration, in spring, and on their 686 Doubt

southern migration, in the autumn. The length of the dotterel is about ten inches. Its plumage in summer is brown on the upper part; the cheeks, throat, and a band above the eyes, white; breast rusty red, with a white gorget on the upper part of it; a conspicuous black patch on the middle of the belly, and a few of the tail-feathers tipped with white. It is tolerably well known in the London market, and its flesh is much esteemed.

DOUAY BIBLE. (See BIBLE.)

DOUBLE BAR, dubt. (Sr. double and barre), in Mus., a term applied to two straight parallel lines drawn close togother perpendicularly through the staff, for the purpose of dividing the various strains of a movement.

DOUBLE BASS, CONTRA BASS, or VIOLING.—The deepest and most powerful-toned instrument employed in concerted music. It so enriches and austains the masses of harmony, as to be indispensable in the orchestra. It has three thick catgut strings, which orchestra. It has three thick catgut strings, which are tuned by fourths, and generally plays from the same book or part as the violoncello, though it is sometimes found necessary to write a distinct part for it. Notwithstanding that all music for the double bass, in common with that for the violoncello, is written in the bass clef, the real pitch of the former instrument is an

DOUBLE COUNTERFOLKT.—When, in two-part composition, the parts are so composed that the upper one may be inverted an octave lower, so as to become the under part, whilst the other retains its place unaltered, it is called a double counterpoint in the octave.

Double Decomposition, in Chem., the interchange of scids and bases which takes place when certain salts are mixed together. Thus, sulphate of potast, on being mixed with nitrate of barvta, is not only decomposed itself, but causes decomposition in the baryta giving rise to sulphate of baryta and nitrate of potash. Double decomposition is resorted to in innumerable instances for the formation of salts, both in the labora-

tory and the manufactory.

DOUBLE ENDING.—When, at the end of a strain, two or more dots, a double bar, and several notes are placed, with a figure 1 over the first and a figure 2 over the second part, it is thus called. It signifies that certain measures are to be repeated, and the part under figure 1 to be sung or played the first time, and that under figure 2 the second. Should the parts 1 and 2 be connected by a tie, both are to be repeated the second time.

DOUBLE FLAT, in Mus., a character compounded of two flats, signifying that the note before which it is placed is to be sung or played two semitones lower

than its natural pitch.

DOUBLE SHARP, a character in Mus., designated by a cross, thus X, used to raise any note an interval of two tones. Neither double flats nor double sharps are ever placed at the head of a staff indicating the signature, but are only occasionally introduced in the course of a composition; for which reason no general staff signature is given to keys requiring more than seven

DOUBLE-SHOTTING .- When ships engage at close quarters, the guns are sometimes loaded with two and

quarters, the guns are sometimes loaded with two and even three balls, when they are said to be double and treble-shotted. By increasing the weight of metal to be discharged from the gun, its destructive power is considerably augmented at any short range. DOUBLE STARS. (See STAR.)

DOUBLE STARS. (See STAR.)

DOUBLE-TONGUING, a peculiar mode of tonguing employed by flantists, which produces a more brilliant and spirited effect, combined with a greater facility of articulation, than the ordinary method. Double-tonguing is effected by the action of the tongue against the roof of the mouth; this action being caused by the roof of the mouth; this action being caused by articulating the word tootle very distinctly, and at the same time accommodating such articulation with the corresponding notes.

DOUBLING THE CUBE. (See DUPLICATION OF THE CUBE.)

DOUBLOON, dub-loom' (Fr. doublon), a Spanish and Portuguese coin, the double of a pistole.

Dount, dowt (Lat. dubito, I doubt), is that state of mind in which we hesitate as to two contradictory conclusions, having no preponderance of evidence in
